All of the studies included in the meta-analysis were with typical groups. Future studies should investigate if MBIs improve the learning of children and adolescents with a clinical diagnoses of learning difficulties or with disorders such as attention deficit/hyperactivity disorder (ADHD) that can impede learning progress. Indeed, previous non-RCT studies have shown benefits in

both individuals with learning difficulties (Beauchemin et al., 2008) and with ADHD (Van der Oord et al., 2012; Zylowska et al., 2008).

Conclusion

There is some evidence that MBIs might be useful in improving learning outcomes as well as a suggestion that effects of MBIs might be sustained and be particularly beneficial under certain circumstances (i.e., if the MBI contains more hours of training and includes younger participants). However, although there has been an influx of recent RCTs, some of which were fully powered, with large school-based representative samples and follow-ups that test the sustainability of effects (e.g., Kuyken et al., 2022; Volanen et al., 2020; Lassander et al., 2020; Dunning et al., 2022a), none of these studies included a measure of learning in their outcome variables, suggesting that improving learning is not a primary focus of current mindfulness research. Indeed, the existing evidence base for MBIs improving learning reviewed here is sparse (in both number and in size of studies) and shows evidence of bias. Although MBI offers some promise in improving learning and sustaining effects over time, all findings should be interpreted with caution.

Appendices

Appendix 1—Table showing effect sizes (Cohen's *d*) immediately after training and at follow-up. Positive effect sizes show superiority of MBI over controls

	<i>Assessment following training</i>	<i>Assessment at follow up</i>
De Voy (2019)1	Versus active study skills: spelling = 0.234, maths = 0.062, reading comprehension = 0.394	Versus active study skills: spelling = 0.328, maths = 0.199, reading comprehension = 0.322
	Versus active muscle relaxation: spelling = 0.136, maths = -0.058, reading comprehension = 0.475	Versus active muscle relaxation: spelling = 0.111, maths = -0.229, reading comprehension = 0.266
De Voy (2019)2	SS: spelling = -0.028, maths = 0.32, reading comprehension = -0.027	SS: spelling = 0.014, maths = 0.178, reading comprehension = -0.049
	Versus active muscle relaxation: spelling = 0.117, maths = 0.345, reading comprehension = 0.211	Versus active muscle relaxation: spelling = 0.074, maths = 0.273, reading comprehension = 0.28
De Voy (2019)3	SS: spelling = -0.028, maths = 0.055, reading comprehension = 0.174	SS: spelling = -0.182, maths = 0.319, reading comprehension = 0.189
	Versus active muscle relaxation: spelling = 0.251, maths = 0.386, reading comprehension = -0.198	Versus active muscle relaxation: spelling = 0.189, maths = 0.266, reading comprehension = -0.117
Flook et al. (2015)	School grades (learning = 0.556, health = 0.554, social-emotional = 0.964, cognition = -0.32, language = 0.092)	
Franco et al. (2010)	School grades = 1.4	
Lassander et al. (2020)	Verbal fluency = 0.017	Verbal fluency = -0.097
Lin and Mai (2018)	Course assessment = -0.32	
Moreno-Gómez and Cejudo (2019)	Verbal fluency = -0.024, reading = 0.03, writing = 0.046, learning problems = 0.647	Learning problems = 0.657
Schonert-Reichl et al. (2015)	Maths grades = 0.38	
Zelazo et al. (2018)	Versus active literacy: literacy = 0.06	Versus active literacy: literacy = 0.178
	Versus passive no contact: literacy = 0.067	Versus passive no contact: literacy = 0.696

Appendix 2—Forest plots

Forest plot showing all MBIs compared to controls in improving learning outcomes. Positive standard differences in means shows superiority of MBIs.

Forest plot showing MBIs compared to active controls in improving learning outcomes. Positive standard differences in means shows superiority of MBIs.

Forest plot showing MBIs compared to passive controls in improving learning outcomes. Positive standard differences in means shows superiority of MBIs.

Forest plot showing MBIs compared to controls in improving learning outcomes at follow-up. Positive standard differences in means shows superiority of MBIs.

Appendix 3—Funnel plots

Funnel plot of publication bias for all MBI studies.

Funnel plot of publication bias for MBI studies versus active controls.

Funnel plot of publication bias for MBI studies versus passive controls.

Funnel plot of publication bias for MBI studies at follow-up assessment.

Beyond play dichotomies

Historically, play has often been described as a mode that constitutes a natural way of being, close to children, innocence, and nature. Play has been perceived as a contrast to school, where pupils have been seen as unduly tamed citizens, colonized by methods that are alien to the child itself. Thinkers like Rousseau and Huizinga, and acclaimed authors like Goethe and Tolstoy, have all foregrounded and celebrated the creative nature of play. Consequently, they have advocated pedagogies that offer leeway for the child's own free roaming, and playful explorations. For instance, on his estate in tsarist Russia, Tolstoy educated the children of poor peasants through Socratic dialogues, play, and creative writing.

Within the history of social sciences, play has been subordinated to instrumental goals. Following Sigmund Freud, Erik H. Erikson, Donald Winnicott and other psychodynamic thinkers, play has been seen as the therapeutic method par excellence in clinical work with children. For instance, play-world methods, which are widely used within child psychology and psychiatry, draw on the basic idea that children display and learn to handle envy, jealousy, and relational difficulties through the use of play. Thereby, play becomes both a diagnostic and therapeutic method. Similarly, play has been advocated as an important method for learning. In both cases, diagnostic/therapeutic or instructional goals are set as the privileged or superordinate goals of play. In much of such work, play has not been studied per se but subsumed under ulterior societal goals, such as diagnosis, therapy, or instruction. Moreover, it is situated within a set of implicit dichotomies that form a hierarchy, where play and exploration are generally cast as what is less "developed" or valuable and that has to be upgraded through connections to what is serious. Within such theorizing, play is often discussed in terms of a number of more or less fixed dichotomies, shown in [Table 1](#).

In this chapter, we explore the ways in which some of these binaries can be seen to dissolve when analyzing children's play in contexts of social interaction. Beyond discussions of fixed binaries, sociocultural theorizing (e.g., [Vygotsky, 1976, 2002](#)) casts play as a basic resource in social interactions in that it is presented as the dominant mode in the child's life. The human being should be seen as a playing creature, someone who has an inborn capacity and predisposition for play, what Huizinga has called *homo ludens*, and this goes for both children and adults. Within sociocultural theory, play thus has a constitutive role for development.

Play, mediation and everyday disputes: Vygotsky versus Piaget

Two of the most influential developmental theorists of the twentieth century, Jean Piaget and Lev Vygotsky, both discussed the role of exploration in children's learning, arguing that playful variations constitute core aspects of learning.

Table 1 Play – work dichotomies.

<i>Play</i>	<i>Work (school)</i>
Exploratory learning	Instruction
Individual	Group work
Fantasy play	Play with rules
Role play	Construction play
Simplicity	Complexity
Improvisation	Rules
Nature	Culture

Piaget (1945) claimed that learning always involves adaptation. From the infant's first attempts at world making, learning and cognition draw both on attempts to mimic others, on imitation, and on play and subjective meaning-making. In his terminology, adaptation thus involves both imitation (accommodation) and play (assimilation). For instance, infants may imitate words of their caregivers but endow them with idiosyncratic meaning. In their very first appropriations of words in their mother tongue, Swedish infants may, for instance, employ *pappa* (daddy) for *lampa* (lamp) as the two Swedish words are phonologically fairly similar, and both phenomena tend to be matters of interest within the young child's world making.

In much of his early work in the 1920s–1940s, Jean Piaget had a phenomenological focus, manifested in a series of ethnographic studies of children as philosophers. His phenomenological period led to extensive theorizing on play with objects, on the basis of observations of his three children's actions in nursery-room contexts (Piaget, 1945). He claimed that concept formation involved a constant balancing (equilibration) between the known and the unknown. The child therefore repeats, experiments with, and recombines what is not yet quite mastered. The learning of a first language is a clear example of the ways in which children learn, not through explicit instruction, but through observations, exploration, and experimenting, which can, for instance, be seen in children's hyper-corrections and other self-corrections (for a review of contemporary work, see Rogoff et al., 2003). Within Piagetian theorizing, such exploratory work characterizes all the semiotic modes of young children – language, art, imitation (including pantomime), and fantasy play (role play) – as well as children's play in construction games (Piaget, 1945). A basic notion is that play is a form of intelligence that is parallel to and equivalent to language, imitation, and art in the child's early development. However, in his theorizing, Piaget primarily cast fantasy play as an aspect of the younger children's early learning.

In contrast, Vygotsky (1976, 2002) located both play and game activities at the heart of his theorizing on children's activities and development. In fact, he theorized play (including games) as something that defines much of the child's imagination and combinatorial thinking. In contrast to Piaget, who did not discuss the role of fantasy play in later learning or modernists like Herbert Read (who have discussed children's art work as something that is arrested through schools and schooling), Vygotsky (2002) claimed that the child's imagination continues to develop all though the school years. This is partly an effect of the fact that mediation is an important aspect of learning in sociocultural theorizing. A given mode of mediation, for example, creative writing, may involve difficulties that the child does not encounter in oral story telling (Vygotsky, 2002). Each medium (e.g., speaking vs. writing, words vs. pictures, virtual play vs. play in "real life") involves its specific difficulties or challenges.

The role of play and games for learning

In Vygotskian theorizing, one important role of teachers and other masters is to build on the children's play activities by introducing topics that appeal to their imagination, and by choosing a type of mediation (drama, play, writing, art work or digital activities) that might appeal to a child in relation to the child's age and prior experiences or a specific area of learning. Today, it can be seen that children spontaneously engage in quite complex cognitive activities when engaging in, for instance, digital activities on the Internet. Play as such involves one type of mediation, what Vygotsky called a 'mental tool' in children's development. This also means that play may boost intellectual development all through life.

Drawing on his work on children's thinking around games with rules, Piaget (1932) presented a model of informal learning and social order, claiming that children of school age develop much of their moral thinking from social exchange with peers and, in particular, from intellectual disputes with peers about games with rules (e.g., marbles). Piaget claimed that peer relations are more symmetrical than adult–child dialogues. They therefore engage more wholeheartedly in critical disputes with peers, challenging the other person's thinking. Thereby, they develop perspective-talking skills in ways that they would not do with adult authorities. In contrast to their conflicts with adults, children who argue with peers tend to engage in more extended and more elaborate arguments. However, even though Piaget emphasized the role of peers for critical thinking, he did not document sibling or peer-play dialogues in everyday life, whereas he did document parent–child-play interactions (Piaget, 1945) and adult–child interviews about games with rules (Piaget, 1932).

In contrast, Vygotsky (1976) claimed that all human behavior and social life includes rules. Therefore, it is not meaningful to cast fantasy play as an activity that is necessarily less complex than game activities or construction play. In Russian, there is moreover but one word, "igra", for both play and games. Vygotsky (1976, 2002) explicitly challenged a major divide between role play and play with rules, as well as any major divide between exploration and instruction. Instruction does not arrest imagination and free exploration. In fact, imagination increases as the individual child appropriates more knowledge of the world.

Vygotsky theorized on the role of apprenticeship in children's learning, and on informal master–apprentice relations that form zones of proximal development, where children may surpass themselves, moving into a higher stage of mental processes, if assisted by a master. He claimed that "In play, a child is always above his average age, above his daily behavior; in play, it as though he were a head taller than himself" (Vygotsky, 1976, p. 552). Play thus constitutes a potential zone of proximal development, where children may assist each other in exploring the world. Moreover, play is about recollections (memory) and this means that children collaboratively advance their imaginative faculties, as they gradually appropriate more knowledge. This, of course, also means that collaborative play may profit from the accumulated prior experiences of all co-present peers.

Whereas Piaget celebrated verbal dispute and the developmental role of games with rules, Vygotsky valued all kinds of play, including fantasy play or role play. Along with Piaget's focus on peer disputes, Vygotsky's foregrounding of language and mediation, and his view that play is the child's dominant mode, have prepared the ground for a novel focus on peer dialogues in children's learning. In contemporary language socialization studies, and sociocultural theorizing, play and play communities have indeed

become central foci, and there is a growing awareness of the role of play for children's learning in peer group and family life contexts (Evaldsson, 2005; Goodwin, 1990, 2006, 2007).

Play as participation

Barbara Rogoff et al. (2003) reviewed the various ways in which children acquire new knowledge without formal instruction, but through keen observations and listening-in, what they called "intent participation." Such informal apprenticeship often takes place in different types of horizontal collaborations, for example, between siblings or peers or with adults if children are allowed to freely watch and listen-in. In contrast to the lesson-style conversational practices that often characterize traditional middle-class adults and their ways of socializing children, for example, at dinner time or in school contexts, such informal apprenticeships may involve keen observations, mimicking, and exploration, rather than instruction. These practices may involve various aspects of children's appropriations of cultural know-how: acquiring a first language, learning other tasks, and the appropriation of local norms for what is an accepted community member.

A substantial body of work on informal practices has been devoted to "participation" and its role in informal apprenticeships, and more specifically, to the ways in which people become fully competent members of specific communities of practice. Lave and Wenger (1991) argued that apprenticeship is linked to membership in communities of practice, where members advance from onlookers and peripheral participants to fully accepted members. They primarily highlighted adult communities of practice, such as alcoholics anonymous, where participants gradually move from peripheral to full participation. In the field of play, such emergent participation may of course also involve informal play communities, related to, for instance, sandbox play (Corsaro, 1979), pog-game activities (Sparman and Aronsson, 2003), computer gaming (Sjöblom and Aronsson 2012a, 2012b) or hopscotch (Goodwin, 2006), that is, various play and game activities where children and young people in informal groups learn from each other within informal communities of practice.

Vygotsky (2002) described children's play products as crystallized imagination. In line with his theorizing, recent research shows that such imagination is not located in a social vacuum. Imagination emerges within a given social order, and it is socially organized. The value that is placed on, for instance, play materials tends to be strictly regulated within local communities of practice, where peers play together and in various ways assess each other's play performances and play materials. Children who, for instance, play with pogs (Sparman and Aronsson, 2003) constantly assess each others' pogs and their trade values in ways that establish local hierarchies of what Bourdieu would call symbolic capital.

Within a sociocultural perspective, children's imagination and increasing skills in play and games are related to their communities of practice, be these related to family life and sibling groups or to peer groups, groups of schoolmates or fellow guild members in, say, World of Warcraft. Intent participation is linked to play communities and play hierarchies in these communities in that key emotions (e.g., excitement, affiliation, disaffiliation) are triggered by the play and games of everyday life.

Play politics

Play politics concerns who gets to play, and even more importantly, who does not get to play. Erving Goffman (1971, 1981) often deployed "play" as a metaphor for social life – for example in his discussions of ratified and non-ratified players and for his analyses of play and by-play – testifying to the basic role of play in social life. Play is both non-serious and serious and, in order to understand its full meaning and seriousness, we have to explore how it is situated in social life.

At first glance, children's play worlds may seem totally free and accessible. Yet one of the first matters to be learnt by young children is how to get access to play – to playmates, to peers' sustained attention, and to play materials. In his documentations of young toddlers' play practices, Corsaro (1979) documented how young children acquired various access rituals for gaining the attention of their (potential) playmates. Drawing on Goffman's (1971) notion of access rituals, he showed how such rituals are learnt through prior successful and unsuccessful attempts at achieving joint attention in play. Thereby, Corsaro also illuminated how even very young children engage in quite complex perspective taking when trying to secure access to ongoing play activities. In her work on mixed-age peers, Whalen (1995) has similarly documented how quite young preschoolers engage in complex tactics, calibrating their play directives in relation to peers' prior utterances, and how they delicately avoid alliances that might upset co-participants (and eventually lead to the arrest of play). It could be argued that children form what could be called play communities, where it is important for participants to be able to take part in local teasing, joking, and other play practices. Obviously, such communities are closely tied to participation, and to local rules for inclusion or exclusion in play (for recent work on school age children's play politics, see Karlsson, 2018).

On the basis of a broad review of prior work on play in different cultures and in contemporary society as well as in historical settings, Schwartzman (1978) has documented how play negotiations take up a great proportion of children's playtime throughout different phases in the child's life, and she has advocated increased attention to issues concerning access to play. These negotiations may concern who gets access to material resources as well as who gets to play what role or in what ways or with whom. Play negotiations – or what we would call play politics – thus concern both physical and virtual play resources. In his work on preschoolers' playful improvisations, Sawyer (1997) observed that young children spent more time than older children on planning, negotiating,

and talking about play. Moreover, he found that friendship had an effect that was similar to age and experience in that friends would go more seamlessly into play, needing less time for planning and coordination.

Research indicates that jokes and playful teasings are important conversational resources for securing participation in local play communities. Teasing, threats, and play politics have been documented in great detail by Marjorie Goodwin, who has analyzed social interaction as parts of her ethnographies of children's play practices in neighborhood and schoolyard areas (Goodwin, 1990, 2006). Over the years, she has analyzed ways in which children and adolescents spend much time, negotiating with each other about inclusion and exclusion and play rules, as well as about material resources. Moreover, she has moved beyond gender stereotypes, showing that both boys and girls engage in insults, gossip, teasing, and other play practices that, at times, border on what is aggressive or violent. In fact, verbal insults, at times, take the form of highly complex entire or partial repeats of prior utterances, where the participants build upon each other's contributions. Through creative repetitions of the prior speaker's insults, a child may thus build on peers' repertoires of invectives and insults, building new and more elaborate versions (Goodwin, 1990, 2006).

Such conversational work can also be seen in the play of preschoolers. Traditionally, Piagetian and other theories on play have generally positioned games and rule play as more complex than fantasy play or so-called imaginative play genres. However, contemporary research, based on video recordings of children's play worlds, reveals a picture where role play might be quite complex, requiring substantial account work, that is, social explanations or reason giving, and other types of mitigations on the part of the participants. On the basis of their analyses of the conversational work of young children in play dyads, Aronsson and Thorell (1999) have shown in detail some of the many ways in which preschool children engaged in quite elaborate perspective-taking in order to negotiate about and solve play conflict scenarios (for instance, involving which play figure – a parent doll or child doll – is to use the only available play vehicle (a bike) for moving in ongoing role play).

Gameplay, animation and learning

Björk-Willén and Aronsson (2014) have documented and analyzed how children "animate" play during gameplay in a preschool context in that they, for instance, talk back to game characters, protesting about their ways of treating the player or their co-players "Listen you duck don't laugh at her!" On other occasions, the children warned game characters "watch out, watch out!" Moreover they animated their conversations during gameplay in a number of other ways, for example, through outcries like "oah pow," "oops," along with "ouch," "WOW" and "oh no, oh NO."

Such blurted affective outcries – what Goffman (1978) has called response cries – thus offer conversational resources for animating play. It can be noted that, along with code-switches, they make it possible for someone to signal a change in footing, that is, in his or her overall orientation to events (Goffman, 1979). Work on children's gaming in the everydayness of their homes has shown that quite young children deploy "response cries" in their gameplay with peers as ways of marking affiliative as well as disaffiliative moves in the game (Aarsand and Aronsson, 2009).

Response cries, laughing and shouting also form parts of the social interaction in youths' gameplay when engaging in World of Warcraft and other computer games, that involve guilds and teamwork (Piirainen-Mars and Tainio, 2009; Sjöblom and Aronsson, 2012a, 2012b). In these game contexts, response cries and other improvised commentaries on the game are important for signaling what is newsworthy or noteworthy in an ongoing game. Such outcries signal affiliation or disaffiliation in ways that make sense to the co-players, but, at the same time, they also form ways of qualifying for participation, that is, for being a fully qualified member of a target team in that they show the player's mastery or lack of mastery in making relevant or irrelevant comments. Moreover, response cries can be seen as the players' resources for orienting to their audience, engaging in action aesthetics, making gameplay more interesting to watch for any co-present siblings or peers. Thereby, it might also be possible to secure the sustained interest and participation of any by-stander to the game.

When the players let out spill cries like "oops!" ("ojdå!" in Swedish) or other response cries, they can be seen to accentuate their shifting affiliations and disaffiliations with other players, but at the same time, they also enhance the dramatic aspects of gameplay. Moreover, they at times animate gameplay talk in that they address the enemy's avatars through aggressive verbalizations, animating the enemy through talking to him as a real person. Apprenticeship in gameplay is not only about playing skillfully, it is also about talking and about joking, rejoicing, making glee or pain cries like someone in the know, someone who is a legitimate participant in the game. In children's gameplay, it is not just the game software that animates gameplay, it is recurrently the players themselves who animate gameplay (Aarsand and Aronsson, 2009; Björk-Willén and Aronsson, 2014; Sjöblom and Aronsson, 2012a, 2012b).

Within the social context of an afterschool gameplay café (game hall) environment, Sjöblom and Aronsson (2012a, 2012b) have moreover shown that youths in their late teens recurrently get engaged in lengthy "negotiations" during the gaming or, soon afterward, about who was to blame for a poor strategy or who was ultimately accountable for that the team lost the game. Another aspect of informal learning in computer gaming is thus how the players engage in negotiations both about what has happened and hypothetical discussions about what might not have happened if a co-player (other member of the same team) had, for instance, not made specific disastrous moves. Such hypothetical talk at times turns into detailed discussions about in what order things "really" happened or why or how something started to go wrong, and who was to blame for the team's failure to win over the enemies in, for instance, World of Warcraft. In terms of reasoning, the players at times engaged in quite complex arguments and counterarguments, and these post-game discussions at times turned into quite sophisticated, somewhat academic disputes.

Language play

Imitation or repetition in classroom contexts has traditionally been seen as an impoverished way of acquiring new knowledge. But in their work on children's language learning and joking in a first-grade Swedish immersion classroom for migrant children, [Cekaite and Aronsson \(2004, 2005\)](#) documented how the children recurrently engaged in repetitions as a type of meta-pragmatic play. Such play took place as indirect playful comments on other persons' ways of saying things. For instance, children enacted performances of the ways in which persons of authority, like teachers, would say something. During informal work in the classroom, the children and their peers also made funny role enactments or teased each other for their "funny" ways of talking. The pupils would, for instance, say something where they spontaneously deployed a "teacher voice," talking in an overly authoritative or somewhat stylized type of teacher voice, and engaging in improvised role reversals. On other occasions, repetitions involved playful and creative recyclings where the children accentuated parts of words that invoked something tabooed. During informal spontaneous conversations in the classroom, peers made such role enactments for the mutual enjoyment of the classroom community. In order to keep conversations going with classmates, the children had to find ways of capturing and attaining the sustained attention of their peers. As noted by [Cathcart-Strong \(1986\)](#) in her discussion of second language (L2) learning in a preschool setting, one of the unwritten conversational maxims of peer group life was to "be entertaining!" In order to recruit play partners, you have to be someone who is fun to play with.

At times, children's enactments involve artful alliteration and other forms of poetics, as well as code switches and variations in pitch, volume, and voice quality. In his original paper on changes of footings, [Goffman \(1979\)](#) discussed code switches as one method for highlighting speaker's playful accentuations of what is newsworthy or remarkable, and code switches have been documented in children's play, for instance in multilingual school settings (e.g., [Cromdal and Aronsson, 2000](#)). Work on playful teasing practices in both gameplay and informal school contexts have shown how children and adolescents create complex tactics, where they build upon prior insults in subtle ways, turning the weapons of their attacker against them as it were ([Tholander and Aronsson, 2002](#)). On other occasions, repetitions merely involved creative partial repetitions of, for instance, teacher talk, accentuating parts of words that invoke something taboo.

In their analyses of a high-school classroom for beginner learners of Swedish as a second language, [Åhlund and Aronsson \(2015\)](#) documented how youths in their teens (16–18 year-old migrants) deployed code switches and stylizations as important resources for creating peer group alignments through joking and laughing together, playfully animating peer's or teacher's ways of speaking that could be seen as noteworthy or laughable. Such playfulness in the classroom was an important part of forming a community of practice in that it generally involved events where the pupils "laughed with" rather "laughed at" each other.

Artful ways of stylizing authorities or of speaking as a teacher (when, for instance, enacting, teacher roles) constitute important conversational resources in classroom performances and classroom struggles about legitimacy as a "clever" student within the local peer group context. Stylizations of teacher talk, or posh ways of speaking English, are deployed by school-age children in their ways of joking with each other and having a laugh, for instance, when deploying mock politeness or mock authoritative fashions of talking to each other. In different ways, these studies all illustrate the need to integrate play in models of language learning.

Learning what?

What do children learn in their play dialogues? Apparently, much of a first language (or a second language in immersion contexts) is learnt through playful imitation (repetitions), and increasingly more complex recyclings and variations. Such informal learning involves different types of renderings, of both what is said and how it is said, that is, matters of style that require so-called pragmatic awareness. Children are neither formally instructed in their first language, nor in how this language should be used in terms of everyday diplomacy or politics, that is, when and how to deploy mitigations or other so called politeness strategies. Yet they obviously acquire quite broad repertoires of styles that can be deployed to upgrade or downgrade the intensity (and offensiveness) of potentially sensitive messages. Play dialogues are important sites for displaying and learning such strategies. If we assume that there is substantial learning through intent participation, it is possible to explain the skills with which even preschool-age children engage in intricate play dialogues, adopting the perspective of others, and predicting the ways in which conversational strategies may upgrade or mitigate potential challenges to the hearer.

In much of the work discussed here, role play certainly appears to be as complex as play with rules in that children have to take into account both their co-participants' past moves, and their projected uptake. At the same time, all of this has to be calibrated in terms of local rules of comportment, and local diplomatic protocols for what might be said and in what ways. Yet, this largely takes place without any explicit instruction. It means that play theories should move away from any rigid dichotomies between role play, on the one hand, and play with rules, on the other. [Vygotsky \(1976\)](#) claimed that there is no major divide between work and play, and in children's lives, play is serious business. Contemporary studies show that play dialogues involve important relational work in that children display and acquire conversational tactics for handling conflicts. As discussed, this can be seen in children's access rituals, negotiations and play politics, as well as in their sustained participation in play activities.

Now more than ever there is a need for effective ways to learn information. Advances in technology, rapid increases in the amount and accessibility of information, and more flexible course delivery methods are bringing forth changes to the landscape of education that raise questions about the best ways to design and deliver instruction. Such questions will most certainly increase as we head into a future that will involve further challenges, uncertainties, and increasingly non-traditional approaches to education.

One of the most valuable things that research can offer to education, therefore, is reliable evidence-based practices that stand the test of time. When it comes to learning, a great deal of scientific effort has been devoted to understanding how the learning process works and how to improve it. In particular, over 100 years of cognitive science research has revealed specific strategies and techniques that substantially and reliably boost student learning, and that can be readily applied in any course material. This chapter reviews two of the most powerful techniques to emerge from this research: *retrieval practice* and *spacing*. The sections that follow include a description of these techniques, the research demonstrating their effectiveness, how often they are utilized by students, and practical recommendations for incorporating the techniques into education.

Retrieval practice

Retrieval practice involves practicing to retrieve information from memory. For example, after reading a section of a textbook chapter on the visual system, a student might lay the text aside and try to recall everything that she has just read. This could include anatomical information about the eye, the function of rods and cones, and visual pathways within the brain. Even if she does not remember everything perfectly, the act of trying to remember it and then checking her accuracy makes it more likely that she will successfully remember that information again in the future.

Fig. 1 shows the design of one recent study on retrieval practice. Rowley and McCrudden (2020) had middle school students learn information about overfishing by first reading a text passage and taking notes over the information, and then completing a follow-up activity in which they either re-wrote the information from their notes or tried to retrieve the information from the passage. On a later essay-type test over the information, the group that practiced retrieval scored significantly higher than the group that re-wrote their notes.

A large number of studies has shown similar benefits of retrieval practice. One of the earliest studies was carried out by Sones and Stroud (1940), who found that seventh grade students learned information about the history of paper significantly better by reading a text passage and then answering questions about it, compared to reading the passage and then rereading it over again. Of particular importance are studies carried out in authentic educational environments showing the real-world advantages of retrieval practice. When compared to non-retrieval-based activities such as re-reading or additional studying of the information, retrieval has produced significant benefits on elementary school students' learning of scientific information (Jaeger et al., 2015), new vocabulary (Goossens et al., 2014), and spelling skills (Jones et al., 2016), as well as on middle and high school students' learning of history (Carpenter et al., 2009; McDermott et al., 2014), social studies (Roediger et al., 2011), and science (Rowley and McCrudden, 2020). Retrieval practice has also been shown to benefit university students' learning in a variety of courses, including biology (Carpenter et al., 2016), psychology (Ebersbach et al., 2020), anatomy (Dobson et al., 2017), and mathematics (Hopkins et al., 2016), as well as medical residents' learning of information about medical conditions (Larsen et al., 2009).

The exact way that retrieval practice is done varies somewhat across studies. Fortunately, the technique is quite robust and can be flexibly adapted in a number of ways. The key element involves having some opportunity to retrieve information that is being learned. This could take the form of practice questions that students work on during class or in a homework assignment, "clicker" questions that are part of the class lesson, or online review questions that students complete outside of class. A variety of different types of questions (e.g., multiple-choice, short answer) are beneficial as long as they require students to retrieve the answers

Fig. 1 Overview of the design from Rowley and McCrudden (2020).

(McDermott et al., 2014). Classroom-based studies have shown consistent advantages of retrieval practice in the form of low-stakes quizzes administered in class or online, with a variety of different question types (Sotola and Credé, 2021).

Many studies have shown benefits of retrieval practice on memory of the same information that was retrieved. For example, if students practice retrieving the English translations for Spanish vocabulary words (e.g., Gato - ?), this will boost their future memory for those same vocabulary words. The benefits of retrieval can also be flexible, however, such that they can apply to situations in which students might need to apply their knowledge to answering a question that they have not seen before. For example, Dobson et al. (2019) had undergraduate students learn texts on physiology topics through reading the texts multiple times, versus reading the texts and then trying to retrieve them. On a test one week later, students recalled more information from the texts that they had learned through retrieval compared to rereading. Retrieval practice also facilitated students' performance on transfer questions that required them to generalize knowledge they learned from the texts. For example, after practicing to retrieve a text containing information about how aerobic adenosine triphosphate (ATP) production is affected by oxygen pressure in the atmosphere, students had more success answering a question about how cardiorespiratory function would be affected by a hypoxic (high-altitude) environment.

Studies exploring the durability of retrieval practice have shown that these benefits are long-lasting. Practicing retrieval at one point in time boosts learning of that information even on a final test that is given several weeks later (Carpenter et al., 2008), or several months later (Carpenter et al., 2009). Thus, retrieval practice is an effective learning method that is flexible and long-lasting, and can be adapted to fit any course material.

Why is retrieval practice beneficial? Researchers have conducted many studies on the theoretical and neuroscientific mechanisms involved in retrieval (e.g., Carpenter and Yeung, 2017; Carpenter, 2011, 2009; Karpicke et al., 2014; Rickard and Pan, 2018; Pyc and Rawson, 2010; Wing et al., 2013). This research has shed light on the mental processes that occur during retrieval and how they contribute to learning. Perhaps of greatest practical importance, one reason that retrieval is beneficial is because it reveals the state of our knowledge. That is, it effectively tells us what we know and do not know. Only by trying—and sometimes failing—to retrieve something can we be aware of what we know (information that we can retrieve successfully) and what we do not know (information that we could not retrieve). Such awareness is critical to successful learning because it identifies the information that is not yet learned and needs to be studied more.

Accurate awareness of one's own knowledge does not occur naturally. Students have a strong tendency to overestimate what they know. For example, in some classroom studies, prior to taking an exam, students are asked to predict what they think their grade on the exam will be. These studies consistently show that students' predictions of their grades are higher than the actual grades that they earn on the exam (Foster et al., 2017; Hacker et al., 2000; Hartwig and Dunlosky, 2017; Miller and Geraci, 2011). The tendency to overestimate one's knowledge is extremely common and has been demonstrated in a multitude of studies, ranging from simple laboratory-based memory tasks (Carpenter and Olson, 2012; Finn and Metcalfe, 2007) to exams in real courses. This tendency extends beyond academic situations too, as surveys of the general public show that people commonly overestimate their own knowledge, skills, and abilities in a variety of domains (Dunning et al., 2004).

Overconfidence is so common, it is possible that it reflects a general "optimism bias" that people adopt without even being aware of it. In the context of a learning situation, overconfidence can be detrimental because a student may choose not to put forth effort into learning something if they believe they already know it. To cease studying prematurely then leads to the unfortunate reality check when students see their exam scores and realize they did not know the information as well as they thought they did.

Retrieval practice provides a simple solution to this all-too-common problem. By using retrieval as a strategy for learning information, students get this reality check at an early stage, well in advance of a high-stakes exam. This allows them to focus their study

efforts where they are needed most, on the information that they were unable to retrieve. Retrieval thus serves as a diagnostic check that helps students guide their learning in a way that maximizes their success. Indeed, research shows that retrieval practice improves students' awareness of their own learning, a key step in guiding study decisions in a more informed and effective way (Agarwal et al., 2008; Little and McDaniel, 2014; Tullis et al., 2013).

Spacing

Learning is not easy. Even if we use the right learning techniques, achieving full understanding of a concept requires us to devote sufficient time and effort to learning it. When we encounter a new concept for the first time, we do not instantly understand it 100%, but instead have to engage in further study, thought, and reflection about that concept.

Perhaps it goes without saying that repeated practice is necessary for learning. However, a question that is not so obvious to answer is how that repeated practice should be scheduled. When learning to apply mathematical formulas to story problems, for example, is it best to practice applying the same formula over and over again right away? Or, should the formula be practiced a little at a time on different occasions?

Given the same overall number of learning opportunities, research shows that those opportunities are more effective if they occur separated in time, rather than immediately back-to-back. This finding is known as the *spacing effect* (also sometimes referred to as *distributed practice*), due to the advantage of repeated learning opportunities that are "spaced out" or distributed in time.

The spacing effect was first reported by Ebbinghaus (1885/1913), who measured his own memory for nonsense syllables and found that repeated attempts to learn the syllables were more effective if they were carried out at different points in time, rather than within the same session. The spacing effect has since become one of the most widely-studied and consistent findings in the learning sciences, having been demonstrated in several hundred laboratory- and classroom-based studies.

In a typical study on the spacing effect, students have two or more opportunities to learn some information. If those opportunities are spaced, they occur at different points in time. If they are not spaced (often referred to as *massed*), the same learning opportunities occur back-to-back immediately. Even though the number of learning opportunities and overall time spent learning are the same in both cases, spaced scheduling leads to significantly better learning.

Fig. 2 shows the design of one recent study on the spacing effect. Emeny et al. (2021) had mathematics students complete 12 practice problems on permutations and Venn diagrams. Following a tutorial on these topics, students worked through four practice problems in each of three sessions one week apart (spaced), or they completed the problems all in the same session (massed). On a test four weeks later containing new problems over these same concepts, performance was significantly greater for students who practiced the problems using the spaced schedule compared to the massed schedule.

A number of additional studies conducted in authentic educational environments show real-world advantages of spacing. For example, spacing has produced significant learning enhancements in a variety of educational contexts, including elementary school children's learning of new vocabulary (Sobel et al., 2011), language skills (Ambridge et al., 2006; Seabrook et al., 2005), and mathematics (Schutte et al., 2015), middle school students' learning of biology (Randler et al., 2008) and mathematics (Nazari and Ebersbach, 2019), and high school students' learning of geometry (Yazdani and Zebrowski, 2006) and French vocabulary (Bloom and Shuell, 1981). Spacing has also been shown to benefit university students' learning of mathematics (Lyle et al., 2020), English language skills (Miles, 2014), and meteorology (Kapler et al., 2015), along with medical students' learning of nutrition (Raman et al., 2010), laparoscopic tasks (Spruit et al., 2015), and surgical skills (Moulton et al., 2006; van Dongen et al., 2011).

The exact way that spacing is carried out varies across studies. Spaced learning opportunities are sometimes scheduled on consecutive days, and other times with longer periods of time in-between such as days or weeks. In studies involving more than two learning opportunities, the time in-between those learning opportunities can also be evenly-spaced (e.g., two days in-between each learning opportunity) or non-evenly spaced (e.g., with the time in-between each learning opportunity increasing or decreasing). Like retrieval practice, spacing is a robust technique that can be flexibly adapted. The key is to arrange the spaced learning opportunities with enough time in-between to allow some forgetting of the information, but not with so much time in-between that the initial learning opportunity has been completely forgotten. Many of the classroom studies on spacing have demonstrated significant learning benefits by scheduling repeated learning opportunities on consecutive days or every few days.

Although many studies show that spacing benefits memory for the same information that was practiced, spacing also benefits the ability to apply the learned information to new situations. In one study (Vlach and Sandhofer, 2012), elementary school children learned about food chains. The children were taught general scientific principles (such as the tendency for larger animals to eat

Fig. 2 Overview of the design from Emeny et al. (2021).

smaller animals) within a particular biome such as an ocean, desert, grassland, swamp, or arctic environment. Four lessons over this information were given during the same day (massed), spread across two days with two lessons per day (clumped), or spread across four days with one lesson per day (spaced). On a test one week later, children were asked to generalize these principles to a biome that they had not previously learned about. For example, if they learned about the grassland biome (and the tendency for a snake to eat a rat) but did not learn about the desert biome, a question on the one-week delayed test asked specifically about the tendency for a particular desert animal (e.g., the scorpion) to eat other desert animals (e.g., lizard, beetle, cactus, or fox). Children performed significantly better on this test if they had received the spaced lessons one week prior, compared to the clumped or massed lessons. Along similar lines, other studies have shown that spacing enhances students' application of other knowledge and skills, such as diagnosis of clinical disorders (Zulkiply et al., 2012) and proficiency at evaluating the credibility of information on websites (Foot-Seymour et al., 2019).

The benefits of spacing are long-lasting, having been demonstrated over time intervals of several weeks (Kapler et al., 2015; Sobel et al., 2011), several months (Carpenter et al., 2009), and in one study up to a year (Cepeda et al., 2008). Thus, like retrieval practice, spacing is an effective learning method that is flexible and long-lasting, and can be adapted to fit any course material.

Why is spacing beneficial? Many studies have looked into the theoretical and neuroscientific mechanisms involved in spacing. These studies have revealed important insights into the mental processes involved in repeated practice and how those processes change when the spacing between repeated practice opportunities is increased (for recent reviews, see Carpenter, 2017, 2021). An early proposal that is still quite relevant today is the idea that spacing promotes students' attention to what they are learning (Hintzman et al., 1973). When students learn something through a spaced schedule rather than a massed schedule, the amount of time spent in a given learning session is shorter. For example, a student who spends a total of 90 min studying anatomical terms could study those terms repeatedly in the same 90-min period (massed) or could study the same terms for 30 min at a time on three different days (spaced). Even when learners try hard to focus on a task, attention naturally declines over time, such that a longer learning session is less likely to receive full attention than is a shorter learning session. Thus, even with sustained effort, students are less likely to be able to devote their full attention to the single 90-min session than to the three different 30-min sessions.

It has also been proposed that spacing is beneficial because it engages retrieval practice (Benjamin and Tullis, 2010). When information is learned in a massed fashion, the same information repeats itself on such a short timeline that the previous occurrence of that information is still fresh in mind and does not need to be retrieved. When information is spaced, however, enough time goes by in-between repetitions such that the earlier occurrence of that information is not still in mind. In this case, a given piece of information (e.g., a foreign language vocabulary item) can remind students, and encourage retrieval, of the previous occurrence of that information. Indeed, studies have shown that spacing is more effective for learning when the spaced repetitions encourage retrieval of the earlier repetitions (Wahlheim et al., 2014).

Retrieval practice and spacing combined

Retrieval practice and spacing can be combined to produce better learning than either technique alone. Although spacing is significantly better than massing even when information is simply presented without requiring retrieval, spacing that involves retrieval practice is even more beneficial. For example, Dobson et al. (2017) had kinesiology students learn information about muscles by reading the information repeatedly, or by reading the information and then trying to retrieve it. Students either read the information multiple times across two or three consecutive days, or they alternated between reading the information and trying to retrieve it the same number of times across the same number of consecutive days. These spaced strategies were compared to a massed strategy in which students engaged in both reading and retrieval of the information all on the same day. On a test over the information given one week later, performance was highest for information learned through reading and retrieval spaced across three consecutive days.

One particularly effective method that combines retrieval and spacing is known as successive relearning. Here, students take some material that they are learning (e.g., foreign language vocabulary) and they practice retrieving it, with feedback, until they retrieve all of the information 100% correctly. Students then repeat the process again for a pre-determined number of times at particular time intervals. For example, Bahrck (1979) had students retrieve Spanish vocabulary words until they got each of them right. Students then engaged in five additional learning sessions in which they practiced retrieving the same words again until they got them all right. These "relearning" sessions either occurred back-to-back (massed), spaced apart by one day, or spaced apart by 30 days. Although it was harder to retrieve the Spanish words every 30 days—that is, students forgot more of the information in-between the learning sessions—the 30-day interval led to superior long-term learning on a final test given 30 days later. A follow-up study showed that the learning advantage for the group that practiced at 30-day intervals was still present even after several years (Bahrck and Phelps, 1987).

Successive relearning at spaced intervals has proven to be quite effective for enhancing students' learning of course information. Rawson et al. (2013) had undergraduate psychology students learn the definitions for concepts (e.g., classical conditioning) by practicing to retrieve them, with feedback, until they retrieved all of the definitions 100% correctly three times. Two days later students practiced retrieving again until they could retrieve each definition correctly one time. Compared to learning concepts through additional study opportunities at the same time intervals, successive relearning resulted in significantly higher exam scores. This was the case even though the exam questions covered the same concepts but were not identical to the practice questions that students encountered during successive relearning. Furthermore, the advantage of successive relearning was still present on a follow-up test over the concepts that was given more than three weeks later.

Students' use of retrieval and spacing

Retrieval practice and spacing are highly effective techniques for boosting learning. We have seen that they are also easy to implement and can be adapted to any learning material. These techniques therefore have great potential to enhance students' academic achievement. However, research indicates that these techniques are underutilized in education.

Some of this research involves surveys in which students are asked about the methods they use to learn information in their courses. About 70% of undergraduate students report using retrieval-based methods such as practice questions (Geller et al., 2018; Hartwig and Dunlosky, 2012). However, when asked why they use these methods, the majority of students report that they use practice questions and other retrieval-based methods to determine how well they have learned the material. This certainly makes sense, as trying to retrieve something is a direct way to see if that information has been learned. Importantly however, this research indicates that students are largely unaware of the direct benefits of retrieval on learning. Indeed, a much smaller portion of students in these studies (under 30%) reported using retrieval-based methods because they believe these methods help them learn. Thus, students view retrieval primarily as a means of checking their learning, rather than as a means of directly enhancing their learning.

Surveys show that students underutilize spacing in their studying. In the study by Geller et al. (2018), only 17% of students reported that they space out their studying over multiple days or weeks. In a study by Corral et al. (2020), only 8% of students reported that they do their studying throughout the semester as they learn the information. These and other surveys show that instead of spacing their studying, students tend to do most of their studying just a handful of days before the exam (Blasiman et al., 2017).

Other research involves collecting observational data on students' choices to engage in retrieval and spacing. In some studies, questions were made available in the form of practice quizzes prior to mandatory exams. Students were given the option to use the practice quizzes if they wanted to, but the quizzes were optional and not incentivized. Because practice quizzes represent a form of retrieval practice, the number of students who choose to complete practice quizzes can give an estimate of how often students engage with retrieval practice. In one study involving a practice quiz in multiple courses, the completion rate of the quiz varied by course, such that the quiz was completed by about 40%–50% of students in psychology courses, about 60% of students in a genetics course, about 66% of students in an ecology course, and 91%–92% of students in medical and zoology courses, respectively (Carillo-de-la-Peña et al., 2009). In other studies, completion rates of an optional practice quiz were about 46% of students in dentistry courses (Olson and McDonald, 2004), and about 75% of students in pre-med courses (Velan et al., 2008).

In other studies, practice quizzes were made available, but in smaller doses such that short quizzes over different parts of the course material were provided at regular time points throughout the academic term. For example, Johnson (2006) provided two optional quizzes over each of 14 textbook chapters in an educational psychology course. In two other studies, a short review quiz was made available to students after each individual class meeting in introductory biology (Carpenter et al., 2017) and introductory psychology (Corral et al., 2020). Students were made aware of these quizzes by the instructors of the courses and were encouraged to use them as a study aid. Even so, the completion rate of the quizzes was quite low. The percentage of students who completed all of the available quizzes was fewer than 10% in Johnson's study, about 30% in the study by Carpenter et al. and fewer than 4% in the study by Corral et al.

What about students' use of spacing? One way to examine this is to look at when students choose to complete practice quizzes. If practice quizzes are made available online after each topic is covered in class, do students complete those quizzes in a manner that reflects spacing (for example, completing each quiz a few days after each topic is covered)? Or do they tend to delay completion of all quizzes until shortly before the exam? Although few studies have tracked the timing of students' completion of optional online practice quizzes, the consistent pattern from these studies is that students tend to delay completion of the practice quizzes until shortly before the date of a mandatory exam or other type of assessment (Corral et al., 2020; see also Lui et al., 2019). Thus, the date of the mandatory assessment, rather than spacing, appears to be a primary factor influencing the decision of when to complete practice quizzes. These studies show that students have a tendency to "bunch" all of the quizzes into a brief time window shortly before they will be tested over the information, which is consistent with an approach based more on cramming than spacing.

Potential reasons for students' study decisions

Why do students avoid retrieval and spacing? Research suggests that these tendencies could arise from students' beliefs about the effectiveness of these techniques. More specifically, retrieval and spacing require effort. It is harder to try to retrieve something from memory than to simply read it again, and it is harder to retrieve something that was seen two days ago compared to something that was just seen a moment ago. The fact that retrieval and spacing involve effort has been confirmed through studies in which students are asked to use these techniques and then report how much mental effort was involved. In these studies, students rate retrieval as more effortful than study (Foster et al., 2018; Hanham et al., 2017; van Gog et al., 2011), and they also rate spacing as more effortful than massing (Kirk-Johnson et al., 2019).

Despite the benefits of retrieval and spacing, there is a common tendency for students to perceive these strategies as counter-effective for learning. For example, Yeo and Fazio (2019) taught participants the solution steps to statistical problems by having them study an example problem with solution steps and then try to retrieve the problem and solution, versus simply reading

the problem and solution steps that were already provided. Afterward, participants rated how likely they would be to successfully recall this information on a later test. Even though participants recalled significantly more of the information on a one-week delayed test if they had learned through retrieval compared to reading (i.e., the usual advantage of retrieval practice), participants' predictions of their own performance were the opposite. That is, participants believed they had learned the information significantly better after reading it compared to trying to retrieve it. Similarly, Foster et al. (2018) found that students who were learning probability problem solutions believed that reading an example problem with solution steps was more effective for learning, compared to practicing to solve the problem by retrieving the solution steps.

Along similar lines, studies of the spacing effect have involved opportunities to learn information through spacing versus massing, and then rating the effectiveness of these methods for learning. In one study, participants were taught to identify the characteristics of different butterfly species (Birnbaum et al., 2013). Participants saw several examples of butterfly species, either presented in a way that the examples representing the same species occurred back-to-back (massed), or with other examples from different species in-between (spaced). On a later test requiring participants to classify new examples from the same species, they performed better if they had learned the species through spacing compared to massing. However, when asked which method they believed helped them learn better, the majority of participants (67%) believed that they learned better through massing. Similar results were observed by Kornell and Bjork (2008), who found that students' ability to classify the painting styles of different artists benefited from spacing compared to massing, but 78% of students believed that massing was as effective or better than spacing. In the study by Emeny et al. (2021), spaced practice led to significant enhancements in mathematics performance, yet students erroneously expressed higher confidence in massed practice.

This research reveals important insights into students' perspectives about retrieval and spacing. Specifically, students find both of these techniques to be effortful and not particularly effective for helping them learn. Recent research has shown that these two perspectives could be related, such that students interpret the effort they experience during learning as a sign that the learning has failed. For example, Kirk-Johnson et al. (2019) conducted a series of studies in which participants learned information (e.g., categorizing different bird families, and reading scientific text passages) through massing versus spacing (Experiment 1), and through retrieval versus reading (Experiment 2). Participants had the chance to experience both strategies (massing and spacing in Experiment 1; retrieval and reading in Experiment 2), and then rated the mental effort involved and the perceived effectiveness of the strategy for helping them learn. Afterward, they were given a new set of material to learn (a new set of bird families in Experiment 1, and a different scientific passage in Experiment 2), and chose which strategy they wanted to use to learn that material. Participants rated retrieval and spacing as more effortful, and less effective for learning, than reading and massing, respectively. Of particular interest, these judgments were linked with participants' decisions of which strategy to use to learn the new information. The majority of participants chose to use massing (68% of students) and reading (69% of students) to learn the new material. Furthermore, the effort involved in using spacing and retrieval was negatively associated with the perceived effectiveness of each technique—that is, more effort invested coincided with perceptions that the technique was less effective—and this in turn predicted participants' decisions about which technique to use. In other words, when learning was effortful it was perceived as less effective, and this influenced students' decisions to use what they believed was the more effective (less effortful) strategy.

Thus, even though retrieval and spacing are quite effective for learning, these techniques do not generally *feel* effective, possibly because of the mental effort they involve. Effort plays an interesting, and sometimes counterintuitive, role in learning. A long tradition of research on “desirable difficulties” shows that the most effective ways to learn are often difficult and require effort (Bjork et al., 2013). Often however, when given the choice students avoid effortful learning situations, opting instead for passive learning experiences that feel smooth and fluent (such as sitting through a lecture or reading over their textbook), but do not actually enhance learning (Carpenter et al., 2020). Such a tendency could stem from a misunderstanding of the role of effort in learning and brings to light the important need to educate students on how to think about and invest effort in order to make the best use of their study time.

Toward successful implementation of retrieval practice and spacing

As demonstrated, students are not naturally inclined to use retrieval and spacing on their own, in part, due to the perceived effort involved and the belief that these techniques are not effective for learning. Further contributing to the difficulty in utilizing these techniques is the fact that they require preparation. Utilizing retrieval practice requires that students have practice questions with good quality feedback. Although some materials may naturally lend themselves to retrieval more readily (e.g., foreign language vocabulary), many others require questions to be generated. Especially when learning material for the first time, students may encounter difficulty or uncertainty in generating their own questions. Along similar lines, spacing requires planning a schedule of when to study, which may be challenging for students if they are uncertain about how best to schedule the spacing of study sessions. Thus, getting students to use retrieval and spacing likely requires instructors to provide the tools to facilitate it.

Fortunately, research has revealed a number of ways that instructors can do this. First, instructors can provide practice questions for students over the content they are learning. Research shows that such questions are effective for enhancing learning whether they are in the form of in-class paper-based questions (Carpenter et al., 2009; Carpenter et al., 2016), in-class “clicker” questions (Mayer et al., 2009; Shapiro and Gordon, 2012), or online practice questions that students complete outside of class (Carpenter et al., 2017; Corral et al., 2020).

Second, instructors can encourage spacing by arranging practice questions and assignments in such a way that previously-learned information is re-visited. Many times instructional materials are set up in a way that does not encourage spacing. Instead, course content is usually “blocked” such that one concept is focused on for a period of time, and then the next concept is introduced and focused on, then the next concept, and so on, without returning to previous concepts. In one recent study, Rohrer et al. (2021) examined middle school mathematics textbooks and found that the ordering of practice problems did not make use of spacing. Instead, practice problems over a given concept (e.g., the Pythagorean Theorem) tended to follow immediately after the chapter on that concept, and practice problems over that concept tended to be grouped together such that a number of problems in a row addressed the same concept. Although such an approach does not make use of spacing, research fortunately shows that spacing can be encouraged by including practice problems from previously-learned concepts into current lessons. For example, Rohrer et al. (2015) observed significant improvements in middle school students’ mathematics achievement by taking some of the practice problems from a given lesson and including them in subsequent assignments over the academic term. Along similar lines, Lyle et al. (2020) found that undergraduate students’ achievement in precalculus was significantly enhanced by completing weekly quizzes that contained practice problems from both current and previous lessons, compared to practice problems from just the current lesson. Implementing spacing in this way is quite straightforward, as it simply involves modifying the schedule of practice problems and could be applied to any academic subject.

Third, successive relearning could be utilized to give students clear and concrete guidance on how to use retrieval and spacing. This method might be particularly useful if students have opportunities to use retrieval and spacing but are not entirely sure how to go about it. By giving students a specific approach to use (e.g., continue practicing retrieval until you get all of the information right), along with a specific schedule (e.g., repeat the process every couple of days), students may find it easier to implement these techniques. Indeed, research shows that providing students with specific guidance about successive relearning increases their tendencies to use it (Dunlosky and Rawson, 2015). The method could be implemented via a low-tech approach in which students make flash-cards and carry out the relearning sessions on scheduled days. Or instructors could make use of available online course management systems and set up the relearning sessions in the form of recurring online quizzes that students complete at scheduled times.

Fourth, making students aware of the benefits of retrieval and spacing could help build their knowledge of the effectiveness of these techniques, and might increase the likelihood that students will use them. In the study by Carpenter et al. (2017) involving biology students’ completion of optional online practice quizzes, after the first two exams students were shown the average exam scores of students who completed the practice questions, which were significantly higher than the exam scores of students who did not complete the practice questions. This coincided with a significant increase in the number of students who completed the practice questions before the next exam. Hui et al. (2021) also observed that giving students individualized feedback about the benefits of practice questions on their own learning led to an increase in students’ decisions to use practice questions.

Fifth, technology can be leveraged to implement retrieval practice and spacing. In one recent study (Cleary et al., 2021), practice questions were delivered to students via smartwatches. Students wore the watches which periodically displayed practice questions over material that they were trying to learn. On a later test, the practice questions led to significantly better memory for the material compared to statements of the same information that were delivered for reading only. This benefit occurred even when students were outside of a supervised class environment and engaged in other things. This study suggests that mobile devices may be an effective tool for delivering practice questions, and the scheduling of such practice questions could be arranged to involve spacing as well. The benefits of retrieval and spacing are due to the processes that these techniques engage, so any mobile device could be utilized to engage these benefits. Indeed, a recent review of the research on educational technology reported that mobile devices can be quite effective for enhancing learning, as long as they engage effective learning principles like retrieval practice and spacing (Yeung et al., 2021).

Finally, instructors can encourage spacing by using cumulative exams. By including exam questions from previously-learned topics, cumulative exams involve spacing of information on the exams themselves, and would also encourage spacing by incentivizing students to continue studying material from previous topics. Consistent with these ideas, cumulative exams have been shown to enhance learning more than non-cumulative exams (Beagley and Capaldi, 2016; Lawrence, 2013).

Summary and conclusions

Retrieval practice and spacing are effective learning techniques with a long history of research supporting their positive effects in educational contexts. Despite the widespread benefits of retrieval and spacing, students are reluctant to make use of these techniques for learning course information. One hindrance to adopting these techniques could be the effort that they involve, and the tendency for students to misinterpret this effort as a sign of ineffective learning. A step forward in encouraging the use of retrieval and spacing, therefore, could be to make students aware of the positive role that effort can play in learning, and to experience for themselves how retrieval and spacing can benefit their own learning.

Given that both techniques require some setup and planning, teachers can facilitate students’ use of retrieval and spacing by providing them with the necessary tools in the form of practice questions, review activities that re-visit previously-learned concepts, opportunities for successive relearning, feedback on their performance, and cumulative exams. Education will most certainly face future challenges and changes that can be hard to predict. By incorporating solid and reliable practices for enhancing learning that are backed by strong research evidence, students and educators can be armed with the tools they need to meet future challenges in a way that promotes durable and meaningful learning.

The purpose of service-learning has always been to impact the thinking, attitudes, and development of students, or as [Stoecker \(2016, p. 5\)](#) states, to “liberate students.” Service-learning has also been accepted and promoted as a powerful teaching and learning approach. Researchers such as [Wade \(2000\)](#), [Billig \(2000\)](#), and [Lake and Jones \(2008, 2012\)](#) have highlighted the potential contribution of service-learning in enhancing the social studies curriculum and developing civic responsibility in students. Service-learning achieves these outcomes by actively involving students in the process of learning; service-learning is experiential learning. As such, many service-learning practitioners and researchers have attributed the beginning of service-learning to the work of Dewey; however, doing so privileges higher education–centric models and federal service-learning programs ([Stoecker, 2016](#)). Additionally, starting with Dewey places emphasis on the learning half of the phrase and Stoecker claims that the real emphasis should be placed on the service half. Also focusing on the service half, in [2010](#), Jacoby and Mutascio stated that higher education was being asked to renew its historic commitment to service-learning by accepting a leadership role in addressing society’s increasing problems and meeting growing human needs. However, if one actually examines higher education’s historic commitment to service-learning, it takes the analyst to the period of time before the establishment of settlement houses in the 1880s ([Stoecker, 2016](#)) and the “unrecognized roots of service-learning embedded in African American social thought and action” ([Stevens, 2003, p. 25](#)).

Beginning with settlement houses, this article provides a historical perspective of service-learning rooted in the African American community. The authors then examine the theoretical underpinnings of service-learning and how it has become a pedagogy used throughout many institutions in the United States. To conclude the article, the authors draw on the work of critical service-learning scholars as they look at the next steps in service-learning and experiential education.

Settlement houses

Toynbee Hall opened in East London on Christmas Eve in 1884 and is considered the first settlement house. However, before it opened, a social movement had been taking place across Europe that “knowledge and understanding are the springs of social action and that the surest way to increase knowledge and promote understanding is to practice the art of living together as neighbors and friends” ([Ellis, 1948, p. 170](#)). Paving the way were Christian Socialists like Edward Denison, Arnold Toynbee, and Samuel Barnett, but this social movement lacked organization and the documentation of those in the movement was particularly scarce. Therefore, much is attributed to Samuel and Henrietta Barnett who opened Toynbee Hall in honor of their friend and fellow social reformer, Arnold Toynbee, who died the previous year at 30 ([Ellis, 1948](#)).

Toynbee was an economic historian at Balliol College in Oxford whose life interest was helping Britain’s growing number of working-class poor by developing trade unions, establishing housing and libraries, and offering them free classes. He also encouraged his students and other social reformers to teach free classes in their own communities to working-class audiences. Barnett’s vision of Toynbee Hall was to have university students (men) from Oxford and Cambridge develop solutions to poverty by witnessing it firsthand by living in the hall, volunteering in the community, and sharing their knowledge ([Ellis, 1948](#)). Toynbee Hall is considered the first university affiliated settlement house.

After visiting Toynbee Hall, Jane Addams and Ellen Gates Starr rented an abandoned mansion in Chicago built by Charles Hull and opened Hull House, the first social settlement in North America ([Hull House Museum, n.d.](#)). Hull House offered childcare for working mothers, kindergarten, help with employment and interviewing, English and citizenship classes, as well as classes in

theater, music, and art. Although Hull House was not affiliated with a university, it helped launch the College Settlements Association in 1894 that linked university affiliated settlement houses across major cities in the US (Stoecker, 2016). The mission of these settlement houses varied from charity, to building the power of the dispossessed, to defusing class struggles while maintaining class inequality (Mieras, 2008).

According to Stevens (2003), at the same time that settlement houses were expanding in the US, “a practical application of experiential learning and education devoted to race and community development, and ideas later associated with service-learning, might be observed in most “Negro” institutions like the church, black colleges, and other civic-minded organizations” (p. 26). Focusing on the years between 1890 and 1930, Stevens explored how the activity of African American women, the agenda of the black women’s social club movement, and African American educators should be seen as philosophical and pedagogical precursors to service-learning.

Black social settlement movement

At the forefront of community service, social welfare systems, and educational programs intended for racial uplift and enrichment, one would find African American women and educators participating in service to their communities (Stevens, 2003). The value of service began in the family, was reinforced in the church, and implemented either formally or informally at most black colleges. Like their white counterparts, black women were social reformers and social change agents who believed in educating, instructing, and caring for the young and old in their communities. Anna Julia Cooper, an educator and social reformer, helped organize the black social settlement movement by forming relationships between black college men and women and their communities to problem solve, address public issues, and provide education on citizenship and democracy. However, the social settlement movement was only successful when the college students learned to speak the language of the immigrant groups and the working poor and demonstrated respect for their social lives.

In the late 19th and early 20th century, Ida B. Wells-Barnett was a prominent journalist, activist, and researcher who was instrumental in the formation of the NAACP (Norwood, 2017; Steptoe, n.d.). After three of her friends and fellow businessmen were lynched in 1908, Wells-Barnett became an anti-lynching advocate and created the Negro Fellowship League, which became a social settlement agency in 1910 focused on criminal justice issues. The League offered educational programs for black migrants and ex-prisoners from Joliet State Prison who had no help reentering society and who were often mistreated by a biased system (Stevens, 2003). The League was a way for the local black community to become involved in education and social action surrounding issues that impacted their daily lives.

During the black social settlement movement, organized social clubs for black women were also forming (Stevens, 2003). In 1896, at a conference held for black women’s social clubs, The National Association of Colored Women’s Clubs was created. Josephine Ruffin’s statement became the mission of this newly formed organization.

The reasons why we should confer are so apparent ... We need to talk over not only those things which are of vital importance to us as women, but also the things that are of special interest to us as colored women, the training of our children, openings for our boys and girls, how they can be prepared for occupations and occupations may be found or opened to them, what we especially can do in the moral education of the race with which we are identified, our mental elevations and physical development, the home training it is necessary to prepare them to meet [the] peculiar [special; difficult] conditions in which they find themselves, how to make the most of our own ... opportunities, these are some of our questions to be discussed.

National Association of Colored Women’s Clubs (n.d., p. 5).

These clubs combined social outreach with education to address issues in their communities. Clubs such as the Locust Street Social Settlement in Hampton, Virginia focused on social services and education for wayward girls. The Working Girls Home Association in Cleveland provided education to black girls and women on how to become proactive in their community and civic life, as well as giving girls a place to live when they arrived in the city. Cooper, Wells-Barnett, and members of the black social settlement movement and black women’s social clubs were able to identify social issues of their day, mobilize community members, and connect learning and action to better their community, thereby implementing the philosophy of service-learning, although not as a formal educational approach.

Black educators

W.E.B. DuBois

Male black educators were as involved as the black women in connecting social action and education to combat impediments of racial progress (Stevens, 2003). A student at Fisk University, DuBois was exposed to experiential education and the ideals of service that had a transformative impact on his life. After graduation he lived and taught in rural Tennessee where he learned to speak the language of the people he wanted to teach and the value of non-traditional education. He used the skills and lessons learned while teaching in Tennessee and applied them to the study of the Philadelphia Negro. Following the Hull House, or settlement house model, DuBois lived in and studied Philadelphia’s Seventh Ward for two years. Through this research he once again experienced

the power of experiential learning, but he also realized that change must take place *in* and *with* the community. While not termed service-learning at the time, DuBois' work shares the principles of service-learning pedagogy.

George Edmond Haynes

George Edmond Haynes, a professor at Fisk University, created an experiential education course that is considered a precursor to the modern service-learning courses. Speaking at the *National Conference of Charities and Corrections* in 1911, Haynes outlined how "the problem of social uplift is so great that, in addition to expert social workers, all Negro ministers, doctors, lawyers, teachers and others should have the benefit of instruction in scientific methods and the new social point of view" (p. 385). He outlined a three-point plan implemented at Fisk, as well as other Negro and White Universities.

First, all Negro students were to be instructed in the issues, conditions, and needs of the people in their communities. Students were required to take courses in the following areas: industrial history, economic theory, sociology, economic and labor problems, social work methods, and History of the Negro in America and the Negro Problem. They also attended expert lectures on the "religious problems among Negroes in cities; delinquents and probation problems; special problems of Negro women in cities; of Negro children; and on Principles of Relief" (Haynes, 1911, p. 385). In their final semester, students spent 10 h per week working with their community on the conditions facing Negro people in Nashville. Building knowledge and training of college students was a huge priority for Haynes. He stated that "if there is any one fact well known, it is that the Negro's situation cannot be helped by inefficient and inexperienced enthusiasts" (p. 387).

Second, promising graduates of Fisk University and other colleges were to be provided further study in New York by the Committee on Urban Conditions Among Negroes (Haynes, 1911). The purpose of this committee was to foster cooperation among existing agencies working among Negroes in urban settings and to discover where additional work was needed, to provide resources to the identified areas in order to remedy the situation, and to further train Negro social workers.

Third, agencies in New York and other major urban cities were to be standardized (would all be similar in the way that the agencies would be established), coordinated, and run by trained workers (Haynes, 1911). Haynes discussed how agencies would work together and share information to improve Negro communities, specifically focusing on housing and neighborhoods, creating employment agencies, thrift agencies and cooperative business enterprises, recreation facilities, religious institutions, and exchanging training methods and practices that work.

Barnett, Addams and Starr, Cooper, Wells-Barnett, DuBois, and Haynes should be considered pioneers in service-learning. They sought solutions to issues, mostly racial issues, in their communities and connected education and service to address them. Steven's (2003) stated that "there are relevant lessons that seem to connect service-learning with the action-oriented expression of African American social thought around the turn of the 20th century" (p. 32). The African American social movement and service-learning share many of the same themes: creating knowledge of institutions and issues, investment in the community, and an understanding and appreciation of the circumstances faced by community members. Stevens argued that, had these scholars and their work been included in mainstream higher education, the knowledge base surrounding service-learning would be more expansive and advanced. Instead, many service-learning scholars and practitioners look to John Dewey for the inspiration and philosophical foundation of service-learning (Stoecker, 2016).

Institutional service-learning

In reference to Dewey, Stoecker (2016) noted "It is odd that institutionalized service learning would claim as its hero someone who did not practice service learning and focused his educational theories on children" (p. 13). In his critique of institutionalized service-learning, Stoecker posited that using Dewey as its foundation meant that higher education never had to change, nor was it responsible for taking action to address social issues. Stoecker argued that traditional service learning benefits students and also reinforces power structures that result in detriment to community partners with limited power and resources. Dewey did not practice experiential learning or engage his college students in service even though he collaborated with Jane Addams by lecturing at Hull House.

Most of service-learning history leaves out the Highlander Folk School and its important role in the civil rights movement (Stoecker, 2016). Already discussed is the absence of African American scholars and the black social movement, but also absent is the work by Native American students who occupied Alcatraz Island in 1969. The 60s and 70s witnessed campus service and activism at its peak. Professors and students focused on issues of poverty, racism, sexism, and other -isms and exclusions in society. "And all of it is completely missing from the official histories of institutionalized service learning" (Stoecker, 2016, p. 15). The *National Service Learning Clearinghouse* (2013) historical timeline, does not mention any of these events.

Scholarship Reconsidered, a 1990 publication by Ernest Boyer set the course for institutionalized service-learning and was "one of the first signs of the institutional colonization of service learning's potential" (Stoecker, 2016, p. 18). The National and Community Service Trust Act was signed into law by President Bush in 1990 and defined institutionalized service-learning.

SERVICE-LEARNING—The term "service-learning" means a method—(A) under which students or participants learn and develop through active participation in thoughtfully organized service that (i) is conducted in and meets the needs of a community (ii) is coordinated with an elementary school, secondary school, institution of higher education, or community service program, and with the community; and (iii) helps foster civic

responsibility; and (B) that (i) is integrated into and enhances the academic curriculum of the students, or the educational components of the community service program in which the participants are enrolled; and (ii) provides structured time for the students or participants to reflect on the service experience.

Stoecker argued that *change* and *action*, which were part of the original principles of community based organizations, were changed to *education* and *service* and that there was no empowerment philosophy that undergirded its foundation. In essence, higher education institutions control how service is defined and how students engage in service. Since 1990, critics of institutionalized service-learning have questioned if there is any learning or service happening and if it is happening, is it any good (Eyler and Giles, 1999). If higher education returned to its historical commitment to service-learning, as Jacoby and Mutascio claimed in 2010, it would mean addressing social issues that are prominent today: Black Lives Matter and racial injustice, voting rights, climate change, healthcare, refugee crisis, income gap, gun violence, hunger and food insecurity, and equality (9 Biggest Social Justice Issues of 2020, 2020). As much as we would like to think that institutions of higher education would embrace engaging in politicized civic engagement, it is well documented that they will not approve such activities for their professors or students (Bickford and Reynolds, 2002; Bringle et al., 2006; Kajner et al., 2013).

Conceptualizing service-learning

Service-learning has a long history in education, particularly at the high-school and higher education levels and, more recently in teacher education programs. It is an approach that emphasizes the importance of grounding learning in experience within schools. Proponents of service learning maintain that children's learning emerges from curricula of authentic and meaningful experiences, purposeful activities, and opportunities for social interaction. More recently, there is increasing evidence that integrating service into the school curriculum contributes to students' motivation and academic achievement (e.g., Dewsbury-White, 1993; Hamilton and Zeldin, 1987; Scales and Roehlkepartain, 2004; Scales et al., 2006). Consequently, it is recognized as an effective pedagogical approach that combines authentic community service with academic learning experiences (Billig, 2004). While service-learning is considered an effective approach across all grade levels, we believe that as a pedagogy, it can even be used in the early grades.

Service-learning is considered a "natural fit" for the early grades (i.e., PK-3rd grade) because of its emphasis on first-hand experiences and active engagement. This is because early childhood educators have long recognized the importance of hands-on learning for young children. Indeed, from the early beginnings of the kindergarten movement, components of a service-learning pedagogy have been the staples of most approaches to early childhood education. Froebel's (1899) "gifts and occupations", together with "gardening and nature study", were used to develop the child according to his nature. Montessori (1966) then recognized that children learn important concepts through their own activity, and used practical life exercise or real world experiences to teach her students. Similarly, Kilpatrick, Dewey, and others were proponents of experiential learning through the use of projects and community-oriented themes. Thus, Dewey's (1918) proposition that kindergarten should be "*more natural, more direct, more real representations of current life*" (p. 117) lends support to service-learning pedagogy with young children.

Typically, service-learning is defined as the integration of community service projects with academic skills and content. It is, however, a broad approach that is applied in different ways across different contexts. As such, service-learning represents a wide array of activities such as projects that entail raising money for various worthy causes (e.g., fundraisers, canned food drives) or advocacy activities such as writing letters to public officials about a community issue or concern. Other types of service-learning include direct service whereby students engage with the recipients of the service activity, and indirect service in which the service is offered to the community as a whole but without any direct interaction with the recipients.

Early childhood teachers integrate such service activities into the curriculum not only in areas such as social studies, but also reading, writing, science, and mathematics. It has been recommended (Lake and Jones, 2012) that in the early grades preference should be given to direct service because it allows children to experience the result of their service efforts. Underlying this recommendation are theories of children's early learning, as well as the theoretical bases of a pedagogy of service-learning.

Theorizing service-learning

The theoretical underpinnings of service-learning was first considered almost three decades ago (e.g., Giles and Eyler, 1994; Saltmarsh, 1996). Initially, attempts to develop a theoretical rationale for a service-learning approach drew on Dewey's (1916) pragmatic philosophy. Dewey's philosophical pragmatism challenged the dualistic relationship between knowledge and experience and argued that reality can and should be changed through reason and action. For Dewey, therefore, knowledge and learning should be connected to experience. Proponents of service-learning claimed that service-learning is a form of experiential learning that relies on reflection. Then, in efforts to legitimize service-learning, they reasoned that the paradigm of pragmatism can be employed as a philosophical underpinning for the approach (Maddux and Donnett, 2015). According to Dewey (1938), "*all genuine education comes about through experience*" (p. 35). In other words, education is a social process whereby learning and knowledge emerge from positive experiences.

Service-learning practitioners and researchers (e.g., [Giles and Eyler, 1994](#); [Maddux and Donnett, 2015](#)) maintain that two of Dewey's primary works, *How We Think* (1933) and *Experience and Education* (1938) offer a plausible theoretical basis for the approach. This is because they address the three fundamental service-learning elements of *experience*, *inquiry*, and *reflection*. For Dewey, learning takes place in the context of experience and interaction, whereby learning is derived through a process of reflective thinking.

Beyond Dewey, service-learning advocates also draw on David Kolb's (1994) work on experiential learning theory. [Kolb \(1984\)](#) posited service-learning in terms of a four-stage cyclical process involving concrete experiences, reflection, abstract conceptualization, and active experimentation. Thus, when they are engaged in service-learning, students first participate in a service experience. Then, through reflection they integrate abstract concepts learned in the classroom and consequently, actively understand their experience. For Kolb (2015) and proponents of experiential education, experience is a fundamental and critical part of the learning process. It is hardly surprising, therefore, that this model is often cited as a plausible theoretical rationale for service-learning as pedagogy. Yet, Kolb's theory has been criticized by educators and researchers (e.g., [Miettinen, 2000](#); [Seaman et al., 2017](#)). The main criticism of Kolb's experiential learning theory is that it lacks empirical support ([Coffield et al., 2004](#)). Furthermore, it has been claimed that it is too eclectic ([Miettinen, 2000](#)), that dimensions of the model do not connect to each other cohesively ([Jarvis, 2012](#)), and that it can be somewhat of a barrier to successful facilitation of experiential learning and subsequent understanding ([Seaman et al., 2017](#)). Thus, a revision of Kolb's model has been proposed ([Morris, 2019](#)), as well as other alternative models (e.g., [Bergsteiner and Avery, 2014](#); [Miettinen, 2000](#)). To date, however, Kolb's model remains the most influential as it relates to experiential learning and service-learning approach ([Seaman et al., 2017](#)).

The work of Paulo [Freire \(1970\)](#) has also been invoked by proponents of service-learning as a convincing theoretical rationale. According to the Brazilian educator's critical pedagogy, education should not only nurture the intellect but also promote emancipatory change. Freire's defining work on critical pedagogy in his *Pedagogy of the Oppressed* (1970) has had a significant impact on education and pedagogy worldwide. According to Freire, teaching cannot be separated from critical analysis of how society works. Thus, teaching should challenge learners to critically engage with the world, which in turn can lead to social change. Like Freire, proponents of service-learning believe that education should be rooted in personal experience leading to a process that enhances community, builds social capital, and action for social change.

Several aspects of [Freire's \(1970\)](#) work contribute to a plausible theoretical rationale for service-learning pedagogy. First, praxis, or action that is informed, was a central concern for Freire. Second, Freire emphasized the importance of situating educational activity in the lived experience of participants. Finally, dialog was significant for Freire because it involves individuals working together and, in turn, individuals reflecting and acting on reality. For service-learning proponents, education should engage participants in problem solving, reflection, social action, and transformation. Processes that, like Freire, view education as a constructive, experiential process.

The perspectives of Dewey, Kolb, and Freire offer theoretical support for service-learning. For some service-learning advocates (e.g., [Erikson and Santmire, 2001](#)), however, psychological theory offers a more plausible theoretical basis. For [Erikson and Santmire \(2001\)](#), Contact Theory (CT) offers a useful theoretical rationale for service-learning. First developed by Gordon [Allport \(1954\)](#), CT suggests that contact between two groups of individuals can promote tolerance and acceptance ([Pettigrew and Tropp, 2006](#)), at least under certain conditions. For example, friendship between members of different groups is a form of contact that can minimize inter-group conflict ([Dovidio et al., 2003](#)), which in turn yields individual benefits in the form of "self-expansion." Viewed this way, CT can be interpreted as a motivational process that encourages individuals to grow and integrate new elements into their lives ([Aron et al., 1998](#)). As such, CT seems to primarily rely on emotional processes as opposed cognitive.

Classic cognitive and sociocultural theories of [Bruner \(1968\)](#), [Gardner \(1987\)](#), [Vygotsky \(1978\)](#), and others also lend support to a service-learning approach. Vygotsky, in particular appeals to proponents of service-learning in early childhood contexts ([Lake and Jones, 2012](#)), presumably because of its emphasis on situating thinking and speaking within the context of activity ([Wertsch et al., 1995](#)). That is, children's cognitive development is embedded in experience (i.e., activity), social relationships, and social interaction ([Lave and Wenger, 1991](#); [Rogoff, 1990](#)). Vygotsky's theory suggests that children can achieve much more when they are engaged in collective activities. Such activities are evident in a service-learning context during which the language that is exchanged within peer and adult-child interaction facilitates both the joint activity and subsequent internalization. Through this co-constructive process, the teacher and child interact to create the zone of proximal development (ZPD). In doing so, they each bring different levels of understanding to any given task and, through a process of interaction, compromise, and shared experiences, reach a new level of understanding ([Goldstein, 1999](#)).

Reconceptualizing service-learning for the 21st century

As the previous sections have suggested, service-learning has historical connections to community and education that began many hundreds of years ago. Starting in the settlement homes, and then through community-school collaborations espoused by Dewey, service-learning has significantly impacted education. This section will examine how we perceive the current adaptations of service-learning and its potential as a pedagogy moving forward out of a pandemic.

A critical service-learning

It has been argued that traditional service-learning has historically placed the emphasis on student learning and outcomes related to student development of new ideas and perspectives in relation to meeting a community need. Service-learning for social justice, however, provided a new means to move beyond just “volunteering” and was “designed to enhance practice through exploration of issues of oppression, individual voice, [and] empowerment” (Maybach, 1996, p. 224).

Scholars such as Artz (2001) have long argued that a serious limitation to traditional service-learning pedagogy is the *service-learning as charity* model often employed in higher education. He posits that this model provides students with opportunities to identify community needs, serves as a way to address the needs, yet often does not provide an outlet for reflection and consideration of the structural forces that perpetuate the injustices. It also fails to provide opportunities to meaningfully reflect *with* the community in which they serve as to why the injustice occurs and how their own (the student’s) individual biases may serve as limitations to social justice.

The foundation for Artz’s (2001) argument was that, “charity, by itself, as a basis for service-learning, will not likely lead to a sustained social critique or action” (p. 240). He noted, “charity frequently denies the possibility of social change by implying that the poor or oppressed are less competent and less able than those who have more social, cultural, and economic capital” (p. 240). Artz also stressed the need to move beyond a service-learning pedagogy that fails to challenge structural forces, and allows for a discourse that promotes mutually inclusive dialog between service-learning students and the *oppressed* in order to promote social action, not charity. Mitchell (2008) similarly argued that the goal of critical service-learning, as opposed to traditional service-learning, is to deconstruct and dismantle power structures that perpetuate the need for service and serve to sustain social inequalities. It is these perspectives that we believe will move service-learning into a new *era*. The Covid-19 pandemic, in particular, has helped highlight the inequalities that currently exist, with homeless shelters filling to capacity and food banks becoming depleted quicker than can be refilled. Service-learning scholars should start to stress the importance of change and how we can work collaboratively with community to enable these changes.

An important point emphasized by Artz (2001), and one that we concur with, is that critical service-learning must be approached with care at the institutional level, as the very nature of critical service-learning hinges on a direct focus on the “relationships between power and culture, communication and ideology” (p. 242), which are often materialized as tensions between the academy and the community. Mitchell (2008) also acknowledged that a critical approach to service-learning may be difficult to implement within institutional and societal structures that are traditionally resistant to social change, yet she predicts that the “promise of the approach” to question the status-quo and activate change will invariably lead to critical service-learning as the “next direction” of the field (p. 62). Mitchell (2008) noted that to successfully engage students in meaningful critical service-learning pedagogy, there must be a redistribution of power among all stakeholders, authentic, reciprocal relationships between students and community, and the precinct of a social change orientation. In order for this shift to occur in tangible ways, recognizing that the academy is not the only holder of knowledge and valuing the expertise and knowledge of community stakeholders and partners as co-educators is necessary.

In critical service-learning pedagogy, it is suggested that the stakeholders are the students, organizations/institutions, and resident community members, including their individual and collective interests and histories. By focusing equitably and inclusively on stakeholders’ agency in the critical service-learning process there is opportunity to evaluate the reciprocity of each stakeholder involved, providing valuable insight into perceptions and meaning that serve to empower. Bringle et al. (2009) identified an Exploitative, Transactional, or Transformational (ETT) Framework of service focused on relationship outcomes ranging from exploitive to transactional to transformational. Much of the experiential learning found within the institution are transactional at best and exploitive at worst.

Moving forward

To develop a community engagement ethic in our students, we need to move beyond these traditional modes of partnership and embrace a more transformational experience for all stakeholders. To do this, it is necessary to include community partners as co-educators, to value community partners as holders of knowledge, and to assess outcomes from an academic *and* community perspective. Furco (2000) indicated that, “Service-learning programs are distinguished from other approaches to experiential education by their intention to equally benefit the provider and the recipient of the service as well as to ensure equal focus on both the service being provided and the learning that is occurring” (p. 12). Equality demands reciprocity and reciprocity requires proximity. As critical service-learning educators, it is our responsibility to promote a climate of *service with* as opposed to *service for*, a proximal relationship between students and the communities with which we work, to dismantle deficit-based structural hierarchies often prevalent in schools and communities, in order to foster inclusivity and equity through an asset-based lens. This asset-based lens becomes more focused when critical reflection is added.

Reflection can be accomplished independently or as a collective endeavor. Yet, however done, reflection demands consideration of one’s internal state (beliefs, feelings, assumptions) and external circumstances (actions, relationships, power dynamics, obstacles). Reflection also “demands a self-honesty and humility that will hold its own against affront from any quarter” (Hall, 2019). As a required component of high-quality critical service-learning, reflection plays a necessary and integral part in helping students connect their own identity to the world around them, think critically about their role in the world, and analyze how their own perceptions and beliefs shape the lens through which they *experience* that world. Kolb’s (1984) model of experiential learning

(see figure below) denotes that reflection is necessary for learners to move from experience to conceptualization and from conceptualization to action.

Although educators recognize the benefits of reflection, it is not often *done well* in the classroom. Too often, students are asked to provide a surface-level summary of their experiences and to make obvious connections to the content, leading to little to no critical reflection, adjustment of perceptions, and/or innovative approaches to problem-solving (Nemeth and Winterbottom, 2015). To address these inconsistencies between what we, as educators, know is best-practice and what we actually see in the classroom, there needs to be a better understanding of what critical reflection is, why it matters to students' learning and community impact, and how to facilitate critical reflection that reaches desired academic, social/emotional, and civic outcomes.

Conclusion and implications

In this article, we have taken a step back and examined the roots of service-learning, the transition via Dewey into the larger community, and the theoretical underpinnings that exist within service-learning in the educational institutions we serve. We believe that as service-learning scholars continue in their work, students are best served by faculty and staff working with them who avoid an already agreed upon definition of social justice in the classroom, which challenges students to consider views of the world that differ from their own. Service-learning seems undeniably well positioned to raise important questions about social conditions, to confront students with diverse ideas about these conditions, and to engage them in considering and weighing evidence about conditions they encounter through their community engaged work. Now more than ever, with the implications of a pandemic that has seen hundreds of thousands lose their lives, while millions more become infected, all partners should consider the service-learning they are embarking on. Critical thinking's emphasis on "examining assumptions, exploring various viewpoints, analyzing positions, engaging in self-reflection, and developing [one's] own perspectives" (Goodman, 2011, p. 40) is ideally suited for students' in the 21st Century, specifically, through an authentic processing of their service-learning experiences in light of existing evidence and competing perspectives.

Introduction

The use of computer simulations and games for educational purposes has increased dramatically during the last decade, following a corresponding increase in the technological capacity to support strategies in pedagogical design, instruction, and learning. This increase has been accompanied by several studies, reviews and meta-analyses of the various learning effects of simulations and games. This article aims to (a) present the major characteristics of simulations and games designed and used for learning, as well as, their hybrid forms, (b) discuss gamification in the transition from simulations to games, and (c) highlight recent findings and challenges for the use of simulations and games in education, especially with regard to inquiry-based learning (IBL) in science education. Even though, games have been traditionally associated with learning through game-based learning (GBL) theory (Li and Tsai, 2013; Qian and Clark, 2016; Wouters and van Oostendorp, 2013), we examine, through the extant literature, whether a transition from GBL to IBL is possible, since science education has been strongly connected to IBL. The ultimate goal is to examine whether the best of these two digital worlds could be combined and offered together, through a hybrid form of a game and a simulation, within the same computer supported inquiry-based learning environment. In this regard, the unique affordances of games and simulations are merged for enhancing learning. In the next section, we present a typology of simulations and games in an attempt to identify the different types of simulations and games, as well as their hybrid types, that currently exist in the extant literature. Then, we report on the relationship that these types of simulations, games, and hybrids have with science learning. Finally, we report on the implications that our review has for science learning and point to unresolved issues for future research.

A typology of simulations and games

Computer simulations and games share some core features but also diverge in several characteristics. Both operate on the basis of models, which are sets of rules that determine how their constituent variables are interconnected, and which refer to the systems that simulations and games represent. These underlying models regulate how simulations and games will respond to user input. A design concern, which has been much more expressed for games than simulations, however, is to weigh the complexity of the represented system against usability—the less complex the system, the easier it is for users to interact purposefully with the game (Lukosch et al., 2018; Wardaszko, 2018). In other words, the amount of story (i.e., background information) for a game should be as little as possible to allow game playing as soon as possible. In the case of simulations, the amount of story needed is usually greater for establishing meaningful interaction. The “richer” (i.e., the amount of information and the diversity of the relations a user can extract) or the less transparent (i.e., how “obvious” are the variables, objects and relations involved to users) a simulation is, the more story will be needed to run the simulation purposefully (Swaak et al., 1998; Zacharia and Olympiou, 2011).

There are several other major differences between simulations and games. First, simulations lack a narrative or scenario, which is a distinctive feature of games (Wilson et al., 2009). Such narratives interrelate three essential game elements: (a) The goal to be accomplished (which is different for simulations); (b) the gameplay with a start and end point that unfolds according to certain rules or constraints (whereas simulations are governed by information than rules); and (c) feedback for monitoring user progress in the form of levels, scores, or leaderboards (Parker and Becker, 2013). Second, games and simulations differ in that games demand decision-making by the user to determine the course of user experience (Lamb et al., 2018; Michael and Chen, 2006). For example, in games the users could proceed in a non-linear way, whereas in simulations users are required to make decisions in a more linear fashion. Third, simulations and games differ in terms of dynamics (i.e., user interaction with the game or simulation) and emotions

(i.e., the affective states that are formed after interaction with the game or simulation). Although both simulations and games use experience to convey meaning, games additionally include design elements for eliciting user emotions to stimulate engagement (Marsh, 2011).

Another major difference has to do with the fact that simulations are strictly tied to reality, which results in imitating how the physical or material world works. The representations used for presenting the objects, processes, systems and phenomena involved are drawn from real life. Games, on the other hand, do not usually have strong ties with reality. In fact, many games are based on fictional scenarios, which involve imaginary objects, processes, systems and phenomena.

In order to illustrate the, sometimes, subtle differences between simulations and games, four examples are provided below. Each example is based on an underlying model of projectile motion. The first figure represents an educational simulation, the second an educational gamified simulation, the third a simulation game, and the fourth a serious game.

Fig. 1–4 employ a model of projectile motion (i.e., 2D motion). The educational simulation in Fig. 1 allows students to manipulate variables to study this model. The PhET gamified educational simulation (Fig. 2) does the same, while adding context (i.e., a narrative scenario that puts a playful context to the model, including a specified goal). It lets you shoot a car (the projectile) out of a canon to see where it lands. While you are challenged to set the parameters so that you hit the target, you manage to study, as in Fig. 1, 2D motion. Fig. 3 depicts “Frog Jump,” a simulation game, where levels and challenge are introduced (e.g., the spacing of the lily pads goes from constant to variable, when you miss a pad the frog falls in the water and has to start over) and feedback is provided (e.g., when missing a jump, the formula to optimize the next attempt is prompted). Again, implicitly you are enacting physics laws of 2D motion. Fig. 4 shows the serious game “Angry Birds” by Rovio. In this game you shoot birds from a catapult to reach the levels’ objectives, which is to destroy all the green pigs that are hiding in shaky constructions. Aside from a playful narrative, game elements include, among others, challenge and levels (e.g., the number of birds is limited, the constructions create obstacles to overcome, pigs come in different sizes and might be harder to destroy, birds have unique projectile attributes), points, and leaderboards. Just like the former cases, the game is physics based and built around a model of projectile motion. Similar to the previous cases, users get to understand through the game, in an implicit manner, the variables (e.g., initial velocity of the projectile, the angle that the projectile is thrown) that affect the motion and trajectory of a projectile. However, this last example was not designed to train users to understand projectile motion beyond what they need to play the game better.

Figs. 1–4 illustrate how both simulations and games are basically a functional representation of an underlying model that shares the same principles. In these examples, the principles are those of projectile motion. When characteristic elements are adapted or added (e.g., narrative, goal, esthetics), the representation of the model can shift toward a playful simulation or a game. In the case of the four examples presented above, we have the educational simulation of Fig. 1 and the serious game of Fig. 4 being the two ends of the simulation-game continuum (if one excludes simulations designed for scientific research and games developed for entertainment as shown in Table 1), and between these two ends, the two hybrids (i.e., an educational gamified simulation, a simulation game) of Figs. 2 and 3. Hybrid forms of simulations and games could emerge by either gamifying simulations or by subtracting game elements from games. In the next section, we present hybrids of simulations and games as identified through the relevant literature. It should be noted that there is no consensus in the literature in terms of the terminology used. We present the most prevalent ones among academic scholars.

Table 1 Comparison between different types of simulations and games across several design parameters.

	<i>Simulations designed for scientific research</i>	<i>Educational simulations (including virtual labs)</i>	<i>Modeling tools with simulation capabilities</i>	<i>Gamified educational simulations</i>	<i>Simulation games</i>	<i>Serious games</i>	<i>Games developed for entertainment</i>
Play or learning as the main design objective	Neither play nor learning	Learning	Learning	Learning prevalent but balanced against play	Learning prevalent but balanced against play	Learning prevalent but balanced against play	Play prevalent; learning may occur as a side-effect of use
Narrative and challenge	Absent	Absent	Absent	Either absent (structural gamification) or present (content gamification)	Present	Present	Present
Modeling options	Research-driven, when present	Absent for simulations with provided experiment setup; present for virtual labs that allow building own experimental setups	Present	Absent	Absent	Absent	Absent
Data extraction and processing taken up by the user	Should allow for research and development purposes	Necessary; should allow for educational purposes	Necessary; should allow for educational purposes	Necessary; should allow for educational purposes	Not foreseen within game flow	Not foreseen within game flow	Not foreseen within game flow
MDE framework	Not incorporated	Not incorporated	Not incorporated	Integrating aspects of MDE framework	Based on the MDE framework	Based on the MDE framework	Based on the MDE framework
Opportunities for inquiry-based learning	Irrelevant	Considerable	Considerable	Considerable	Existing	Existing	Irrelevant
Iterations determined by	Variable selection	Variable selection for simulations with provided experiment setup; model building and refinement for virtual labs that allow building own experiment setups	Model building and refinement	Variable selection	Simulation constraints	User actions in the gameplay	User actions in the gameplay
Course of user experience	Pre-defined or partly determined by user actions	Pre-defined for simulations with provided experiment setup; partly determined by user actions for virtual labs that allow building own experiment setups	Partly determined by user actions	Mostly pre-defined	Mostly pre-defined	Partly determined by user actions	Partly determined by user actions

Note: MDE: Mechanics, Dynamics, and Emotions Framework (Robson et al., 2015).

Hybrid forms of simulations and games designed for learning

Although simulations were first employed for research purposes and games for entertainment, there were versions of both simulations and games designed and used for educational purposes. Apart from educational simulations and serious games, which have been the archetypical versions of simulations and games, respectively, to serve educational purposes, there are also hybrid, in-between forms, which attempt to employ and marry the unique affordances of both simulations and games (e.g., modeling tools with simulation capabilities; gamified educational simulations; simulation games). In this section we present core characteristics of educational simulations, serious games, and hybrid, in-between forms (see Table 1).

Educational simulations allow users to change one or more values of variables and then investigate the effect of this intervention on values of other variables built in the system (de Jong, 2011). They may even allow the building of different scenarios or setups. For instance, in the case of science education, users could use virtual labs that allow building different experiment setups, before starting to investigate relationships between variables (Zacharia, 2007). Virtual laboratories are a specific form of educational digital simulations, which can be combined with software scaffolds and other applications to provide a holistic learning experience (de Jong et al., 2021). Although educational simulations allow users to explore the system freely, the underlying model cannot be changed by users, and user experience is largely pre-defined. In the case of virtual labs, however, the possibilities may increase. For instance, there are virtual labs that allow the building of different experiment setups, which allow the user to switch from one underlying model to the other, or even create their own model which, of course, follows the already pre-determined algorithms. In addition, there are modeling tools with simulation capabilities. These tools provide users with modeling options for model building and refinement (see, for instance, GoModel; <https://www.golabz.eu/app/gomodel>). In this case, the course of user experience is partly determined by user actions, as in the case of the virtual labs. This latter characteristic is also found in serious games (see below).

Educational simulations may be enriched with game design aspects (i.e., game-based mechanics, esthetics, and game thinking), an instructional design approach which aims to facilitate user engagement and which is termed “gamification” (see Darejeh and Salim, 2016; Hamari, 2017). Gamification may employ points, badges, and leaderboards (Brom et al., 2019). These elements do not affect content and are characterized as *structural* gamification. *Content* gamification employs game-elements like narrative and challenge, which are expected to not only foster user motivation but also to enhance metacognition (Anderson and Barnett, 2013; Hou, 2015). Gamified educational simulations may display characteristics of structural and content gamification separately or in a way that complements each other.

Simulation games are full-fledged games engaging students in problem-solving tasks organized around a core challenge or mission (Hong et al., 2020). Simulation games incorporate in their game mechanics and dynamics a full content gamification which unifies both the user’s role and decision making (user input), as well as the processing of user input to deliver the system output. Since most simulation games are rigid-rule games (Gust and Klabbers, 2005), the gameplay is largely pre-determined by simulation constraints. Serious games, instead, evolve around more open-ended tasks (for a discussion of simulation games and serious games see Kurbjuhn, 2012). Serious games often have a real-life operational task as their topic (e.g., how to act in emergency situations; e.g., Steinrück et al., 2020). The adjective “serious” is meant to denote that learning is prevalent in serious games, although it is balanced against play (Prensky, 2001; Michael and Chen, 2006).

Learning with simulations, games, and their hybrid forms

Simulations, including virtual laboratories, are considered most useful for promoting inquiry-based science learning (Hovardas et al., 2018). IBL is currently among the most advocated educational strategies for teaching science across K-16 (Pedaste et al., 2015). Its main goal is to have students simulate the methods and practices that scientists follow in order to learn (for details on IBL, see Pedaste et al., 2015). Using simulations in an IBL context requires students to assume the ownership of the learning process by formulating their own questions or hypotheses and to collect data to address them (de Jong, 2019). Simulations, including virtual laboratories, allow students to identify and select variables to perform their investigations and enable them to manipulate the values of independent variables and examine the effect of this manipulation on the values of dependent variables (de Jong et al., 2013).

A series of recent studies, focusing on educational simulations and applications hosted in the Go-Lab ecosystem (www.golabz.eu), showed promising results. For instance, the inclusion of virtual laboratories and applications for preparing experimental designs and constructing graphs in digital lessons was found to enhance the corresponding student skills (e.g., Efstathiou et al., 2018; Xenofontos et al., 2020). Given that IBL is a complex and demanding procedure, software scaffolds are usually employed to support students (Zacharia et al., 2015). Of course, scaffolds can be adapted to learner progress (de Jong, 2019) by fading out when students no longer need the support provided. Some web-based applications with authoring tools offer teaching analytics functionalities to let teachers evaluate the guidance planned for their students in their IBL educational designs (Sergis et al., 2019). These developments increase the capabilities of teachers to enact formative assessment in web-based learning environments and better support their students’ educational paths. However, the need for support in IBL also raises concerns as to why guidance is needed for IBL to deliver its expected positive outcomes (e.g., Aditomo and Klieme, 2020).

Despite the complexity of enacting IBL, even when it is computer supported, researchers and educators are strongly advocating its enactment for science learning purposes (e.g., Alfieri et al., 2011; Furtak et al., 2012; Minner et al., 2010). For instance, the use of simulations in an IBL context was found to be more or equally conducive to student science learning, as opposed to using physical counterparts/manipulatives for experimentation purposes, across K-16 (e.g., Zacharia et al., 2012; Zacharia and de Jong, 2014; Zacharia and Michael, 2016). As a result, IBL is considered by now as an integral part of an individual’s science learning. The question that is raised at this point is whether games or hybrids of simulations and games could also be situated in an IBL context and enhance student science learning.

The use of games and game elements (gamification) for learning (GBL) have also been found to have a positive effect on students' learning outcomes. GBL has been recently documented to deliver a range of desirable learning outcomes, including cognitive, behavioral, and affective effects (Clark et al., 2016), which paralleled previous findings (e.g., Connolly et al., 2012). Further, GBL has been found to promote the development of 21st learning skills (Qian and Clark, 2016). The literature on GBL singles out flow (Chang et al., 2017), competition (Chen et al., 2020) and narrative (Naul and Liu, 2020) as major strengths of games, which may promote cognitive (e.g., achievement and retention) and non-cognitive goals (e.g., enjoyment).

Well established psychological theories provide explanations for how effective learning mechanisms are triggered by games and game elements (Sailer and Homner, 2020; van Roy and Zaman, 2017). The engaging effect of games is commonly explained using Self-Determination Theory (SDT) (van Roy and Zaman, 2017). SDT explains that engagement is the result of an internal drive to fulfill a set of basic psychological needs: competence, relatedness, and autonomy. To foster this kind of engagement in games, designers employ multiple "mechanics" (systems of elements and rules) that appeal to these needs. For instance, game elements such as badges appeal to the need for competence, leaderboards or collaborations appeal to the need for relatedness, and choices (when to play or where to go next) appeal to the need for autonomy.

In addition the success of the game depends on an opaque interaction between the mechanics, the behavior of the player (dynamics), and the emotions that these components evoke (according to the Mechanics, Dynamics and Emotions (MDE) framework, see Robson et al., 2015). Mechanics concern the model that shows how the game works, in terms of its elements, rules, goals, and progression. Dynamics occur through the interaction of the mechanics and the user. However, it is hard to predict how this interaction will evolve due to other unforeseen variables that might become involved by bending or breaking, for example, the mechanics. Emotions concern the affective state that the user is at in regards to the mechanics, dynamics, and content of a game.

The engaging effect of GBL has been confirmed in science education as well, with game flow being positively correlated with reflective processes (Hou, 2015). However, similar to IBL, GBL benefits from support for students during and after the gameplay, like scaffolds and reflection tasks targeting specific knowledge and skills (Iten and Petko, 2016), to safeguard learning objectives and facilitate transfer (Ter Vrugte and de Jong, 2017). In this regard, possible trade-offs between game design aspects and learning outcomes should be considered (Imlig-Iten and Petko, 2018; Landers and Landers, 2015; Ter Vrugte and de Jong, 2017). Designers should take into account that instructional add-ons could distract users from the flow of simulation games (Erb, 2015) or serious games (Baker and Delacruz, 2016). In addition, challenges posed to students and instructional support need to align with their current level of skills so that flow and engagement are maintained (Qian and Clark, 2016; Yen and Lin, 2020). Depending on the level of skills, specific support might have a unique or even disruptive effect (see Ter Vrugte et al., 2015, for an example in GBL). A similar concern is that the net effect of game elements like goals, rewards, and feedback needs to be carefully examined, as far as their overall effect on cognitive load is concerned (Brom et al., 2019).

Although IBL has been strongly advocated for science education (Li and Tsai, 2013), GBL has not, partly because it has not been advocated for and linked with IBL. Some initial attempts have shown considerable potential (e.g., Taub et al., 2018) but more research is needed to substantiate this synergy. The integration of IBL and GBL is expected to accommodate a balanced contribution of both play and learning in student experience (National Research Council, 2011). Such an integration should also incorporate an appropriate level of guidance provided to students in the form of instructional support (e.g., Ter Vrugte and de Jong, 2012, 2017; Wouters and van Oostendorp, 2013). In our view, one way to link IBL to GBL is through the identification of overlaps between the processes involved for their enactments. For instance, both IBL and GBL involve data collection and processing within each of their iterations. Of course, as user immersion in simulation games and serious games increases, as compared to gamified educational simulations, data selection and processing for IBL would require a reallocation of time-on-task toward inquiry activities, which might compromise user immersion and flow. This is an issue to be addressed by future research.

Implications and recommendations for future research

The salience of educational simulations and serious games has risen sharply during the COVID-19 pandemic, which, in 2020, impacted more than 1.5 billion students globally. Simulations and games could be employed to lead science learning and inquiry enactments under the restrictions imposed during this crisis. However, more research is needed to identify how simulations, games or their hybrids could be used to enhance students' online science learning experiences. It is quite clear from the literature that the more we move toward the game end of the simulations-games continuum, the less we now in terms of enacting games and their hybrids in an IBL context. This is a result of researchers and educators' failure to examine the possibilities of using games or hybrids in an inquiry context. We believe that this is feasible for hybrids, since they have a significant overlap with simulations, which have been successfully used in IBL context. In the case of games, it becomes harder to understand whether games could be grounded in IBL, due to the absence of research evidence. Thus, this is a vital area for future research.

Although educational simulations have been well situated in an IBL context, we are still missing pieces of the puzzle concerning the integration of GBL with IBL. For instance, it would be insightful to investigate if simulations, games, and their hybrids could be employed in science education and if GBL could be combined with IBL. Would it be as easy to do so in all cases, or would it be easier through the use of the hybrids? Needless to say, research should be employed to answer these questions and to shed light on possible trade-offs that GBL and IBL could suffer. For instance, immersion and flow (sought for GBL) could be jeopardized (in an integration of GBL with IBL), while trial-and-error user behavior (the usual heuristic in GBL) would compete with the identification of variable relationships through systematic experimentation (as practiced in IBL).

The idea of combining simulations and games is to bring the best of both these worlds into students' science learning experiences. Both of them offer unique affordances that have been found to positively influence science learning. The issue now is how to combine the two digital worlds in ways that optimize students' science learning. This is an agenda for future research.

Introduction

Using and applying strategies to learn new information in a content domain have been investigated in the literature for decades. The terms “using or applying strategies” refer to an intentional conscious action undertaken by learners. Such a definition refers to at least two kinds of strategies, the *cognitive* strategies that are used for learning new information, and the *metacognitive* strategies used for regulating the use of cognitive strategies. Cognitive strategies include examples such as rehearsing and elaborating that can be used to learn new information; whereas metacognitive strategies include planning which strategy to use and when to apply it, as well as monitoring and evaluating one’s understanding. Regulation requires processes such as self-assessment, deciding which strategy to use based on the goal of learning in that instance, and so forth. In short, strategies for learning are distinct from strategies for regulation of learning. The focus of this paper is on cognitive strategies for learning (specific strategies referring to what learners actually do will always be italicized).

Cognitive strategies generally refer to efforts undertaken by learners or students to increase their learning of a given content domain of new information, such as learning expository information about Civil war history or learning procedural knowledge on how to solve geometry problems. The term “learning” has been used broadly in many laboratory studies to mean memory retention of words, facts, and procedures, instead of learning with deep understanding of difficult concepts and processes. Learning with deeper understanding is the goal of classroom instruction, especially in higher education and STEM (science, technology, engineering and math) disciplines. Thus, the goals of classroom instruction are often different from many laboratory studies. This discrepancy between what is measured in many laboratory studies (memory retention) and the goal of instruction (deeper learning), especially in college STEM classrooms, will be noted throughout this chapter.

Many cognitive strategies have been studied for decades, and many meta-analyses have been undertaken (Donker et al., 2014; Fiorella and Mayer, 2016; Hattie, 1996). On the whole, there is no question that using cognitive strategies enhances learning, especially during initial learning of new information, which is the focus of this chapter. But the crucial questions are: Are some strategies better for learning with deeper understanding than other strategies? If they do have differential effectiveness, how can we tell which strategies are more or less effective?

There are many ways to evaluate or predict the potential effectiveness of a learning strategy. One way is to analyze its underlying cognitive processes. For example, the category of “elaborating” strategies, with examples such as summarizing and paraphrasing, involves the processes of “building internal connections between the items to be learned and already existing knowledge,” according to Donker et al. (2014, p. 3). However, it is not easy to know that these two strategies map to the underlying processes of “building internal connections between the items to be learned and already existing knowledge,” since cognitive thinking processes are not directly observable, especially in a classroom context. Other considerations and methods used for evaluating the utility of a strategy include the ease with which students can be trained to adopt the strategy (Fiorella and Mayer, 2016), the ease of implementation in

classrooms (Dunlosky et al., 2013), the age group for whom they are suitable (Brod, 2020), and so forth. The most optimal evaluation method is to seek empirical evidence for a strategy's effectiveness by comparing them side-by-side, as in the case of many laboratory studies.

In this chapter, although we prioritize the importance of having empirical evidence for determining the utility of a strategy and appeal to the possible underlying cognitive processes, we point out a major flaw in the literature for determining effectiveness by contrasting it with an alternative strategy or control condition. This flaw will be pointed out below. We propose, instead, to analyze the utility of a strategy from the perspective of a new theory of how students engage to learn, called ICAP.

Using ICAP, we illustrate how the effectiveness of a variety of strategies can be evaluated without relying on empirical findings. These strategies are chosen using several informal criteria such as: (a) strategies that do not require technology support nor advanced preparation by the teachers (as those may not be easily implemented in a classroom), (b) evidence-based effective strategies (i.e., those that have been investigated in laboratory studies), (c) strategies that are commonly used in classrooms, and (d) strategies that students often utilize (a criterion also used by Dunlosky et al., 2013). We arrived at 50 examples of strategies.

The ICAP theory

ICAP is a theory of cognitive engagement and it provides a framework that outlines different levels of student engagement and learning. ICAP focuses on classifying students' engagement with instruction rather than classifying instructors' instructional objectives or assessment items as commonly discussed in the literature (Bloom and Krathwohl, 1956; Dick and Carey, 2005; Krathwohl, 2002). Moreover, ICAP has a unique approach that uses student behaviors and student-produced outputs for assessing students' engagement level.

ICAP distinguishes among four modes of cognitive engagement: *Interactive*, *Constructive*, *Active*, and *Passive*. The taxonomy of the four modes is discussed in detail along with extensive supporting evidence from the literature in the work of Chi (2009), Chi and Wylie (2014), Fonseca and Chi (2011), and Chi et al. (2018). Four criteria, presented in Table 1 (left column), are provided to facilitate a more accurate discrimination of learning strategies from each mode, because some criteria are more salient for discriminating between one mode from another for some strategies, whereas other criteria are better at discriminating the modes of other strategies. The four criteria are: (1) physically overt behaviors, (2) visible outputs produced, (3) additional focusing or re-focusing on selected parts of the instructional materials, and (4) outputs contain new information. Caveats of each mode are also mentioned.

These four modes are briefly described next, along with their plausible underlying cognitive or thinking processes relevant to learning. We propose that learning involves these six elementary, knowledge-change thinking processes (Chi, 2021): receiving and storing new information, activating prior knowledge, connecting new information with prior knowledge, changing some parts of prior knowledge, inferring from new information and/or prior knowledge, and reflecting on new information or prior knowledge.

Passive

The *Passive* mode of cognitive engagement refers to learners' overt behavior when they are oriented toward instruction (i.e., commonly thought of as paying attention) without producing any outputs. For example, listening to a lecture without taking notes, reading a textbook without highlighting, or watching a video without taking notes, would be considered activities in the *Passive* mode of cognitive engagement. Because learners are not producing any outputs, they are not focusing on a selection of the

Table 1 Four criteria to discriminate among the ICAP modes.

Criteria	ICAP mode			
	Passive	Active	Constructive	Interactive
Physically overt behaviors (include talking and writing)	<i>Oriented toward instruction</i> (or paying attention)	<i>Manipulating</i> some aspects of the instructional materials	<i>Generating</i> based on some aspects of the instructional materials	<i>Reciprocally co-generating</i> from each other's contributions, which were based on some aspects of instructional materials
Visible outputs produced	No	Yes (often)	Yes (often)	Yes (often)
Additional focusing or re-focusing on selected parts	No	Yes	Yes	Yes
Outputs contain new information	No	No	Yes, produced by an individual	Yes, often produced by partners jointly

instructional materials involved, nor any new information produced. So, *Passive* mode has only a physical behavior component or criterion feature (see [Table 1](#), Column 2). When students are not paying attention, then they are not even engaged with instruction, such as when they chat with a friend, doze off, or talk on the phone.

When students are engaging in *Passive* activities, such as watching a video, ICAP assumes that students' cognitive processes are likely to only be receiving information and presumably at best storing it in their memory probably in isolation, meaning it is not connected to some other relevant prior knowledge. A caveat about the *Passive* mode is that, when students are not displaying any overt behaviors other than attentively listening or watching, they could be covertly engaged in deeply processing information, such as inferring, reflecting, or connecting new information with prior knowledge. However, ICAP makes the probabilistic assumption that when students are being *Passive*—not displaying any overt learning behaviors while learning—they are more likely to be engaged only in the thinking processes of receiving and storing.

Active

The *Active* mode of cognitive engagement occurs when students display the overt behavior of physically manipulating instructional materials, such as highlighting or underlining specific sections of a text ([Katayama et al., 2005](#)), pausing and rewinding sections of a video ([Chi et al., 2008](#)), copying verbatim portions of the problem solution steps ([VanLehn et al., 2007](#)), or choosing a justification from a menu ([Conati and VanLehn, 2000](#)). The overt outputs are the highlighted or underlined sentences, the replayed portions of the video, and so forth.

Manipulation often requires students to select portions of the materials, such as selecting a specific sentence or passage to underline or selecting which parts of an instructor's presentation to copy. Selection can often be made based on syntactic cues in the text, such as signaling an important principle, putting important information inside a box, and so forth. The consequence of selecting in manipulation is that it allows students to re-focus on that selected information, thereby paying more attention to it.

Although students do produce overt outputs, the outputs do not contain any new information beyond what was already presented in the instructional materials resulting from the physical behavior of manipulating that the *Active* mode affords. For example, the underlined sentences were already in the text, and the justification chosen from a menu was already provided.

The underlying knowledge-change processes associated with the *Active* mode can be surmised to be activating prior knowledge relevant to the selected and focused parts of the instructional materials, facilitating the encoding of new information to be connected with the activated parts of prior knowledge.

In short, the four criteria of *Active* engagement are: some physical manipulation of some selected aspects of the instructional materials, resulting in visible outputs that can lead to re-focusing, without producing any new information when compared with the given instructional materials. These four criteria are listed in [Table 1](#), under the *Active* column.

Constructive

The *Constructive* mode of cognitive engagement refers to overt behaviors in which learners generate or produce an output that goes beyond what is already provided in the instructional materials, such as a concept map, a diagram, or an explanation. Re-focusing is involved in that the output is generated from some selected aspect of the instructional materials. Finally, the output must contain additional information not included in the available course material or instructional content.

For example, suppose a student is reading about a historical account of an event in a history textbook ([Wineburg and Martin, 2004](#)). If a student starts to create a timeline in his or her notes that sequences the dated events mentioned in the course content (such as the year and actions taken by different historical figures discussed), the student would have produced something that was not present in the instructional materials, but all the information was already provided. This would be an example closer to a manipulative activity, because the student physically created a timeline, in much the same way as students plotting a graph from a provided data set. However, if the student, in addition, enhanced the timeline with some cause-and-effect relations because the sequencing of events allows her to see plausible antecedent causes, then this timeline activity is more generative, and she is thereby engaging in a *Constructive* mode. In contrast, if the textbook provided a diagrammed timeline of events and the student copied the timeline into their notes without making any changes, the student would only be engaging in an *Active* attending activity. Thus, producing an external output per se is not necessarily engaging in a generative activity (i.e., engaging in the *Constructive* mode), unless new information is present in the visible output.

The key knowledge-change process involved in the *Constructive* generating mode is inferring. That is, to generate knowledge that has not been presented, students need to focus on an aspect of the instructional materials and generate new knowledge from either prior knowledge, prior knowledge connected with new information, or new information per se. For example, the *Constructive* activity of self-explaining engages the inferring process ([Chi, in press](#)).

A caveat for the *Constructive* mode is that, even though it requires students to be generative beyond the course content or instructional materials, the *Constructive* mode does not require students to create novel or profound information. Rather, outputs produced in the *Constructive* generating mode only define new information in relation to the course materials. For example, a learner could generate a new idea by inferring a connection to an everyday example while reading a course textbook. The generated new idea is novel to the learner herself, but may not be novel to the content domain. For example, after reading about the septum in the heart in the context of a passage about the circulatory system, a student might wonder about whether the septum is solid or porous. If the student eventually concludes that the septum is solid, this information is new to the learner and not stated in the text passage, but

not novel to the topic of the human heart. Another caveat is that the new information the learner generated is most likely new information the learner induced, and not retrieved from her prior knowledge. See the *Constructive* column in [Table 1](#).

Interactive

We define the *Interactive* mode as overt collaborative dialoging among two peers or more. Although interactions can occur in other ways, dialoging or conversing is the most prevalent. The dialogs themselves can be considered overt outputs, such as explanations and feedback given to each other. In order to engage in the *Interactive mode*, each partner must also engage in the *Constructive* generating mode, bringing new information into the conversation; additionally, each partner must build on the other partner's contributions. Because both partners are *Constructive*, and moreover, because they each can build on the other's partner's contributions (i.e., being reciprocally co-generative), it is plausible that the outputs they jointly produce may contain ideas that neither partner could have produced alone, thus resulting in innovations. See [Table 1](#), the *Interactive* column.

One caveat about the *Interactive* mode is that the dialogs are more likely to be co-generative if a significant amount of turn-taking occurs. This is because more frequent turn-taking allows each partner to incorporate her partner's understanding of the domain into her own thinking and make more frequent adjustments to her own mental model ([Chi et al., 2017](#)). With few turns, essentially, the two peers are each giving mini-lectures, instead of building off of each other's contributions. Such reciprocally co-generative mutual exchanges of ideas can be manifested in several types of standard and conventional dialog patterns, such as defending or arguing a position in a debate ([Schwarz et al., 2000](#)), asking and answering each other's questions ([Webb, 1989](#)), and elaborating on each other's contributions, such as clarifying, building upon, correcting, and so forth ([Hogan et al., 1999](#)).

Criteria for discriminating between modes

Some criteria in [Table 1](#) are more salient than others for identifying the mode of an activity or strategy, or for discriminating among some of the modes. The *Passive* mode is the only one without visible outputs, so the availability of visible outputs is the most salient criterion. The critical criterion for the *Active* attending mode is whether the produced outputs contain some information that has already been presented in instruction, thereby allowing students to re-focus on this selected information. The critical criterion discriminating between an *Active* attending and a *Constructive* generating activity is whether the outputs from the activity contain information beyond what was provided in the instructional materials. This could be a minute inference or it could be a larger unit of knowledge. Finally, the critical criterion discriminating *Constructive* from *Interactive* is whether the new information co-generated in the *Interactive* mode could only be produced by both peers in a reciprocally co-generated way. This determination may be difficult to make, so one may have to rely on other behavioral features, to be explained in another section below.

The ICAP hypothesis

ICAP assumes a hierarchical relationship among the modes based on the behavioral definition of each mode. That is, each mode subsumes the other, such that reciprocally co-generating (the *Interactive* mode) requires students to also be generative (*Constructive*), and generating also requires students to be re-focusing and attending to information (*Active*). In addition, one could postulate the same hierarchical relationship among the four ICAP modes based on the underlying knowledge-change processes. In short, the ICAP hypothesis proposes that the *Interactive* mode can result in the highest level of learning, followed by the *Constructive* mode, followed by *Active*, followed by *Passive* as the lowest level of learning ([Chi, 2009](#); [Chi and Wylie, 2014](#)). Moreover, because only the *Constructive* and *Interactive* modes require inferring and going beyond the course materials, there is a bigger gap in learning between the two "higher" (*Constructive* and *Interactive*) modes compared to the two "lower" (*Active* and *Passive*) modes. We could assume that engaging in the two higher modes promotes deeper learning whereas engaging in the two lower modes promotes shallower learning. Thus, both the behaviors and the plausible underlying cognitive processes implicate the hierarchical relationships of the ICAP hypothesis.

There are two important caveats to note about the ICAP hypothesis. The first is that the deeper learning achievable in the *Constructive* and *Interactive* modes can only be detected if deeper assessment questions are designed to test students' understanding, such as questions that ask students to explain the cause of a historical event, when the cause was not stated, or to reason about the consequence of a historical event. Shallower question, those that typically ask students to recall some information, are perfectly adequate for detecting learning from the *Passive* and *Active* modes. The second caveat about the ICAP hypothesis is that it does not make predictions about learning outcomes for engagement within the same mode, yet there can be large differences in the actual processing of engagement within a single mode. For example, asking students to self-explain while reading a text is a *Constructive* activity, and so is the task of designing an experiment. However, self-explaining takes less processing efforts than designing an experiment, if we consider the amount of time as an indicator of effort, even though both are within the *Constructive* mode. Thus, ICAP's predictions of students' learning levels are reflective of learning levels between ICAP modes, and not within ICAP modes.

Using the ICAP theory to evaluate cognitive strategies

In this section, we use the operational definitions provided for each ICAP mode to determine which ICAP mode a learning strategy or activity likely belongs, as the mode it belongs to predicts its effectiveness for learning. In [Table 2](#), we identify 50 strategies that

Table 2 50 Strategies investigated in the literature.*Passive strategies (5)*

Salient criterion: any outputs produced?

1. Reading and re-reading (Rawson and Kintsch, 2005)
2. Observing, watching, and looking (Cocco et al., 2021)
3. Listening (Feng and Webb, 2020)
4. Tactile learning (Savaiano et al., 2016)
5. Turn-taking reading (since, as a whole, each individual student speaks aloud only for a short portion) (Duffy, 1983)

Active strategies (20)

Salient Criterion: any outputs produced that are present in the original instruction?

1. Clickers and polling (Arthurs and Kreager, 2017)
2. Copying (VanLehn et al., 2007)
3. Enacting: enacting how fast a ball moves or the slope of a line; mimicking; or show the slope of a line with arms (Fiorella and Mayer, 2015)
4. Gallery walk (Chin et al., 2015; Namaziandost et al., 2018).
5. Highlighting and underlining (a selected passage or equation), clip-and-paste (Ponce and Mayer, 2014; Bauer and Koedinger, 2007; Katayama et al., 2005)
6. Identifying a flaw (Friesem, 2019)
7. Listing (generating a list) from memory (Epstein, 1969; Roberts, 1972)
8. Mapping or aligning two sets of given information: this includes matching, choosing an option (Yin et al., 2005)
9. Measuring and other lab activities (Yaron et al., 2010; Tobin, 1990; Aladejana and Aderibigbe, 2007)
10. Ranking (Lombardi et al., 2021)
11. Reading a selected passage or sentence out loud [reading an entire passage would be passive], recite a poem (Pergams et al., 2018)
12. Recall (Endres et al., 2017)
13. Rehearsing (Oberauer, 2019)
14. Review (Cho and MacArthur, 2011)
15. Total physical response (e.g., having students stand or sit for answering true false, students walk to different corners of the room to represent different answer choices) (Asher, 1966, 1969)
16. Guided notes with fill-in-the-blank (Kotsopoulos et al., 2021; Konrad et al., 2009; Austin et al., 2002; Neef et al., 2006; Ponce and Mayer, 2014).
17. Summarizing by deleting irrelevant information (Reilly et al., 2017; Low and Over, 1989)
18. Following step by step instructions (Liefoghe et al., 2018)
19. Modeling, plotting or graphing (Balwaria and Bavishi, 2014; Doer and Zangor, 2000)
20. Testing and re-testing, interleaved testing (Rawson and Dunlosky, 2012; Roediger and Butler, 2011)

Constructive strategies (20).

Salient Criterion: any outputs produced containing information beyond the instructional materials?

1. Analogizing (Gentner et al., 2003; Chinn and Malhotra, 2002; Gentner and Hoyos, 2017; Hoyos and Gentner, 2017)
2. Comparing and contrasting: to derive similarities and differences (Schwartz et al., 2011; Hoyos and Gentner, 2017)
3. Critiquing or criticizing (Okada and Simon, 1997)
4. Justifying (Asterhan and Schwarz, 2016; Lin and Lehman, 1999; May, 2015)
5. Organizing (categorizing, putting in table format, putting events in a time line, etc.) (Donker et al., 2014)
6. Concept-mapping (Chang et al., 2002; Novak, 1990a,b)
7. Drawing, graphing, imagining, visualization (diagrams or other representations, or images, not already presented) (Fiorella and Zhang, 2018; Martin and Schwartz, 2014; Schwamborn et al., 2010)
8. Explaining to another (Roscoe and Chi, 2008; Biswas et al., 2005; Lombrozo, 2012; Coleman et al., 1997; Fiorella and Mayer, 2014; Legare and Lombrozo, 2014)
9. Integrating two or more sets of information or ideas to arrive at a third set; integrating two single or multi-media sources (Britt and Sommer, 2004; Rouet et al., 1996; Butcher, 2006; Bodemer et al., 2004; Mayer, 2005)
10. Posing questions to others, to self, or to authors (Beck et al., 1997; Morris and Chi, 2020; Mestre, 2002)
11. Predicting the outcome of a demonstration (Brod et al., 2018; Schauble et al., 1995)
12. Self-explaining and elaborating (Chi et al., 1989, 1994, Chi, in press)
13. Taking notes or paraphrasing in one's own words; writing an interpretive summary (Trafton and Trickett, 2001; Bretzing and Kulhavy, 1979); writing an interpretive review (Cranton, 2001; Doctorow et al., 1978).
14. Connecting theories or course concepts with everyday examples (Kothari et al., 2019; Rathburn, 2015)
15. Designing experiments in inquiry learning (Ariyawong and Phongsatha, 2017; Gao, 2015; Lombardi et al., 2021).
16. Hypothesizing explanations for a set of data (Hulsizer et al., 2018)
17. Modeling: aligning data with theories (Lombardi et al., 2021); deriving equations from data (VanLehn, 2013).
18. Reflecting and re-assessing one's own understanding to look for gap, coming up with the "muddiest" point (Akhtar and Saeed, 2020).
19. Solving challenging problems with real world scenarios, such as in project-based learning (Fortus et al., 2004)
20. Debugging and troubleshooting (Li et al., 2019; McCauley et al., 2008)

(Continued)

Table 2 50 Strategies investigated in the literature.—cont'd*Interactive strategies (5)*

Salient Criteria: both partners must be reciprocally co-generative and the outputs produced cannot be produced by a single partner (These two criteria are stringent and difficult to assess).

1. Asking and answering each other's questions (Rivers et al., 2017; Webb, 1989); or reciprocal questioning (King, 1990a,b); asking each other for justifications and explanations (Okada and Simon, 1997)
2. Debating with a partner, offering claims and justifications (Schwarz et al., 2000; Okada and Simon, 1997; Darby, 2007; Roy and Macchiette, 2005)
3. Improv theater (Rossing and Hoffmann-Longtin, 2016; Berk and Trieber, 2009; Hoffmann-Longtin et al., 2018); jazz ensemble (Larsson and Georgii-Hemming, 2019; Sawyer, 2008)
4. Peer tutoring (Beasley, 1997; Mastropieri et al., 2003)
5. Reciprocal learning or teaching (Whalon and Hanline, 2008; Palinscar and Brown, 1984)

have been investigated in the literature. For each mode (except the *Interactive* mode), we use its most salient criteria, based on the nature of the outputs (a combination of the second and fourth criterion listed in [Table 1](#)), to determine the ICAP mode of a strategy. These most salient criteria are listed under each mode in [Table 2](#).

Passive mode strategies

The most salient criterion for the *Passive* mode is whether students are producing any outputs while they are paying attention (we assume that students in all the modes are paying attention). We ignore situations in which students are not even paying attention, as that means students are not even engaged. Using these criteria, [Table 2](#) lists five learning strategies that can be determined to be *Passive*. That is, in silent reading, listening, watching and so forth, in which students are merely oriented toward instruction and not doing anything else nor producing any outputs.

Active mode strategies

For a strategy or activity to qualify as engaging students in the *Active* attending mode, students must be producing some physical manipulations, either with or without outputs, but the outputs are part of the original instructional materials. In [Tables 2](#), 20 learning strategies are listed that likely engage students in the *Active* attending mode. These 20 strategies seem obviously *Active* because students are actively manipulating instructional material, often resulting in re-focusing on a selected portion of the instructional information. From this list, total physical response, such as raising hands or stand up/down (*Active* Strategy #15), do not produce any outputs per se, but in responding, students are re-focusing on the questions asked. Clicking on clickers to choose an answer (*Active* Strategy #1), is also physically manipulative, but it also produces an output, the output is an option among the choices provided. For a third example, when students are asked to align two sets of given information via matching (*Active* strategy #8), they are overtly selecting information from one set and linking it to information in a second set by drawing a line or writing out the alignment while not producing any new information or ideas in the process. Similarly, when students are asked to fill out guided notes with fill-in-the-blanks (which typically require students to recall key terms to fill in the blanks), the key terms have already been presented during the lecture or within the instructional materials.

A caveat about these *Active* strategies is that, although they tend to elicit *manipulative* responses, students, at times, may go beyond the task by generating additional information. For example, while summarizing, a student may decide to paraphrase a portion of the paragraph for better clarity and flow, which would turn the *Active* task of summarizing into a generative one. As another example, students may improvise and fill in the blank with their own answers instead of following the prescribed lecture. But overall, if students perform these 20 strategies as designed and expected, then they are likely engaging in the *Active* mode.

Constructive mode strategies

As stipulated in our salient criterion in [Table 2](#), in the *Constructive* mode, the operational criterion is that students are typically generating external information not presented in the instructional materials, or that goes beyond the instructional materials. In [Table 2](#), 20 cognitive strategies are listed that likely engage students in the *Constructive* generating mode because some new knowledge beyond instruction is produced. For example, in analogizing, a new analogy or relations between analogies are produced; in comparing-and-contrasting, new similarities and differences are produced; in justifying, new reasons or justifications are produced, and in organizing, a new organization structure is produced.

A similar logic goes for assuming that strategies such as concept-mapping, drawing diagrams or graphs, explaining-to-another, integrating two sets of information, justifying, posing questions, predicting, self-explaining/elaborating, taking notes are all strategies that are clearly generative in the sense that students are creating some visible outputs or products containing information not already presented in instruction.

There are several caveats that are more relevant for strategies in the *Constructive* mode, although they can apply for the other modes as well. These caveats are addressed below.

Compliance

Just because an activity or strategy expects students to be generative does not guarantee that all students will comply by generating new information. The caveat is that students can instead produce information that does not go beyond instruction, thereby they are responding in the *Active* attending mode. For example, if students are drawing diagrams similar to ones already presented in the text, then they have essentially just copied the diagram and did not generate new information and, thus, are not responding in the *Constructive* generating mode. That is, students can respond in a higher mode (such as responding generatively to an *Active* elicitation, as pointed out in the caveat above for *Active* strategies) or respond in a lower mode (such as manipulatively to a *Constructive* elicitation), as the copy diagram example illustrates. The non-correspondence between the mode of students' responses and the mode elicited, can be determined by analyzing students' responses. However, by-and-large, instructors can only hope that the majority of students do respond in the mode a learning strategy elicits, as it is too difficult or too time-consuming to monitor compliance, either in real time (in a classroom context) or in the context of homework assignments. The important point is that, even without 100% compliance, strategies designed to elicit a generative response will enhance learning more so than strategies designed to elicit a manipulative response.

More or less complicated processing

Although the *Constructive* strategies listed in Table 2 all satisfy the criteria of generating outputs beyond instruction, they do differ substantially, depending on the amount of materials to which a strategy is applied or the amount of time needed to process the information (such as coming up with a solution). The amount of materials can vary within a strategy as well as between strategies. For example, take the strategy of integrating two or more sets of information (#9). The two sets of information can be two sentences, two paragraphs, or two pages. This difference will obviously show that integrating two pages might take more time and is more complicated than integrating two sentences. "More complicated" can be measured in a number of ways, such as the amount of instructional materials a strategy applies to or the amount of time it takes to complete. Thus, "more complicated," obviously means that they take longer to do (sometimes multiple days), thus requiring multiple processing steps, and typically encompass deeper understanding of a larger body of knowledge, in order to be able to carry it out. These strategies, include: coming up with the "muddiest" point of the class instruction (#18), hypothesizing for a set of data (#16), modeling or aligning data with theories (#17), writing an interpretive review (#13), and a variety of other complicated tasks, such as designing investigations and experiments (#15), often involved in project-based (#19) and other forms of robust inquiry learning (#15). A complicated engaging task, as described above, often requires multiple external steps, and numerous repetitive internal thinking processes, in contrast to engaging in simpler *Constructive* strategy on a smaller unit of knowledge, such as self-explaining one sentence, which requires a simple inferring process. The point of this caveat is to explain that ICAP cannot make accurate predictions of learning levels within a single mode, as the processes could vary considerably because of the variations in the time and the number of instructional materials involved. Instead, ICAP is only intended to make learning comparisons among modes.

Invisible thinking processes

In carrying out a *Constructive* strategy, it is possible for students not to display any outputs. For example, a learner can imagine or visualize a diagram without actually drawing it. However, for many of the strategies we described above, some externalized outputs are required, but this requirement does not preclude students from not complying and carrying out generative thinking processes covertly.

Generating vs. retrieval

Another caveat is that for some strategies, we cannot determine whether students' outputs actually generated new information or merely retrieved prior knowledge. Again, the liberal assumption is that for the majority of time, students in the *Constructive* mode are generating new knowledge rather than retrieving prior knowledge, as they are engaged in the context of learning new information.

Interactive mode strategies

To collaborate in the *Interactive* mode means that the interactions must be co-generative, meaning that each partner is being generative beyond the information provided in the instructional materials. In addition, to be reciprocally co-generative means that each partner must build on some selected aspect of the other partner's contributions. We can surmise that the five types of interactions mentioned in Table 2 for the *Interactive* mode are likely to meet these requirements. For example, in debating, each partner is generative in supplying a rationale or justification for defending his/her own point; moreover, each partner often builds on the other partner's points by refuting it. However, in order to be certain, one must analyze the process and content of the dialog patterns.

The process and content of a dialog pattern refers to how and what each partner contributes in a dialog turn. If we categorize the contribution of each partner in one turn of any hypothetical dialog, we can come up with 15 types of dialog patterns. For example, partner 1 can give an *Active* comment such as "I agree," "That's what I believe," and partner 2 can be *Constructive*, with comments

such as “What do you think might happen if we did this?” or “I suspect this might happen if ...”. This exchange would be an example of an *Active-Constructive* (A-C) dialog pattern. An A-A dialog pattern is one in which neither partner made any substantive comments that went beyond either what the instructional materials already provided or beyond what the other partner has contributed, but instead, merely re-described either what was already presented in instruction or what one’s partner said. A C-C dialog pattern involves both partners each *generating* beyond the information provided, but neither of the *Constructive* comments were generated upon the contribution of the partner. Using the four ICAP modes to describe each turn of a dialog gives rise to 15 type of dialog patterns (see Chi and Menekse, 2015). Thus, using ICAP modes to categorize each partner’s contribution shows clearly that only one out of 15 dialog patterns are truly co-generative. This suggests that it is difficult to obtain true *Interactive* collaboration in the ICAP sense of reciprocally co-generative.

Reciprocally co-generative means that each partner is selecting and building upon by inferring some aspect of the partner’s contributions, which may already have been inferred information beyond the information provided in instruction. Because each partner can come up with or infer some ideas that the other partner did not think of, these kinds of ideas are innovative, in the sense that these ideas could not have been generated by either of the partners alone. However, it would be extremely difficult to determine whether an output from collaboration was made jointly or whether one of the partners could have generated it alone.

It is therefore extremely difficult to ascertain, in practice, whether collaborators are interacting in the reciprocally co-generative way, without fine-grained analyses of their dialogs to see how an innovative output is produced. However, there are two options to assess in practice (such as in a classroom) whether collaborators are truly *Interactive*. First, one can rely on gross behaviors, such as sitting and facing each other, gazing at partner, talking to partner, taking turns, pointing and looking at where a partner points, and so forth. Second, instead of identifying dialog patterns by the contribution of each individual turn, we can identify three types of overarching non-co-generative, dialog patterns that we will refer to as: *cooperate*, *dominate*, and *parallel*. In order to understand these overarching collaboration patterns, we need to further introduce the notion of interaction, meaning whether one partner is having conversational (or other types of) exchanges with another partner. For example, the parallel collaboration pattern refers to two of our 15 dialog patterns, such as C-C or A-A. That is, both partners are working either *Constructively* or *Actively*, but they are not interacting in the sense of co-generating or building on the other’s contributions. In the other instance, they can each be *Active* by manipulating aspects of the instructional materials, such as when both students manipulate the lab equipment, but each student measures a different aspect of the lab equipment. A second overarching pattern is that the partners do interact, but one partner dominates the other partner. This usually means, in the literature, that one partner is doing all the work and all the talking, and basically takes control of the task. If the dominant partner is *Constructive* and the other partner merely supports and agrees with the dominant partner, the dialog pattern from an ICAP perspective is either C-A or C-P. The third overarching pattern is referred to as cooperation, which means that the two partners agree to divide a problem or a task up so each partner works on a separate component of the task or problem. In cooperation, there are no interactions between the partners, aside from the initial interactions to negotiate and agree upon what subcomponents to assign to each partner.

In short, although the *Interactive* mode has the greatest potential for promoting deep learning, it is difficult to achieve and ascertain that the students are collaborating *Interactively* in the reciprocally co-generative sense. However, one can assess in practice how *Interactive* partners are by their gross collaboration behaviors and by the three gross types of interacting patterns. In addition, one can anticipate more reciprocal co-generation by designing collaborative tasks that require generative outputs (to prevent parallel manipulation), that are not decomposable (to prevent cooperation), and that are sufficiently difficult that students cannot solve it alone (to prevent parallel generation or one partner dominating).

Evidence in support of ICAP hypothesis

Now that we have illustrated how the mode of a strategy can be determined based on the criteria listed in Table 2, we can verify whether ICAP’s predictions are true by studies that contrasted strategies from different ICAP modes. Because the majority of studies in the literature compare two strategies (that is, comparing a treatment condition with a control condition), we can make many pair-wise comparisons that are consistent with the ICAP hierarchy, such as comparing the *Interactive* mode with the *Constructive* (I vs. C), or comparing the *Constructive* with the *Passive* (C vs. P), with predictions that *Interactive* would be better or more effective for learning than C ($I > C$), and *Constructive* more beneficial for learning than *Passive* ($C > P$), and so forth. Such comparisons across all combinations of pair-wise comparisons have been reported in Chi (2009) and in Chi and Wylie (2014). However, in Chi and Wylie, we focused only on three strategies: self-explaining, concept-mapping, and note-taking. Here we will illustrate a few other examples by selecting studies that we have not described in prior papers, focusing on more difficult tasks at the college level, whether on learning or problem solving.

First, performing in the *Interactive* mode should be better than in a *Constructive* mode. In a study by Okada and Simon (1997), students were asked to solve a molecular genetic discovery task, so this was a *Constructive* activity because they had to derive a new solution that was not shown previously. Pairs of students succeeded better on solving the task (and focused more on alternative hypotheses and justifying their thought processes) than individual students working alone, suggesting that $I > C$, assuming that the individuals were trying to be generative.

Second, the *Interactive* mode should also be better than the *Active* mode for learning. In a reciprocal teaching context, one group of students practiced reciprocal question asking about a text (a generative activity), in addition to other *Constructive* activities, and the other group was locating information from a text (a manipulative activity). The reciprocal teaching group performed better in reading comprehension than the group that only practiced locating information in a text ($I > A$, Palinscar and Brown, 1984).

Third, undertaking a strategy in the *Constructive* mode should be better than a strategy in an *Active* mode. In a study by Britt and Sommer (2004), students were given two texts to read. The first group of students read two texts with instructions to focus on comparing and contrasting the texts and then answered some short-answer questions after each text, clearly a *Constructive* generating activity. A second control group just read the two texts, clearly a *Passive* attending activity. The results showed that the first group was better able to integrate the two texts than the second group ($C > P$, Britt and Sommer, 2004).

Fourth, a strategy in the *Active* mode should be clearly better than a strategy in the *Passive* mode. Many studies make such a contrast. For example, in a study by Kotsopoulos et al. (2021), in a calculus classroom, students in one group used guided notes to fill in the blanks for implications, connections, solutions, while the instructor was annotating or writing on a screen during class, so essentially students could copy the instructor's work, making this a manipulative strategy (*Active* mode). This group was compared to a group from a prior year, in which the instructor only lectured without providing any guided notes for students to fill out (*Passive* mode). The Guided-note group learned to solve calculus math problems better than the group without any guided notes ($A > P$).

Although the studies we cite typically compared two ICAP modes, there are a few studies in the literature that compared three conditions (Bretzing and Kulhavy, 1979; Gobert and Clement, 1999; Coleman et al., 1997) and one that compared all four ICAP modes (Menekse et al., 2013). The results of all four studies support the ICAP hierarchical predictions.

Conclusion: the value of ICAP

Although many strategies have been studied in the laboratory and all have been hailed as effective learning strategies, ICAP shows that these studied strategies are distinctly different in terms of their ICAP mode and thereby in terms of their effectiveness for learning. The *Active* strategies are good at enhancing recall and retention of relevant information, whereas the *Constructive* strategies are good at promoting deeper learning, with the *Interactive* strategies having the potential of creating innovations. The reason that so many studies in the literature have found so many strategies to be effective (Table 2 lists a sample of 50 strategies), is because their effectiveness was compared to a weaker control, meaning a control condition that utilizes an activity that is either in the *Passive* mode or a lower mode than the mode of the treatment condition. The four studies cited in the preceding section, as well as all the others cited in this chapter and earlier papers, all achieved a beneficial outcome of the treatment strategy because the treatment strategy was compared to another strategy of a lower ICAP mode. In order to claim that a strategy is absolutely effective, a study needs to compare it with another strategy at the same ICAP mode, as well as other strategies at the higher ICAP modes.

To illustrate this point with a popular conceptual phenomenon, it has often been shown that when children manipulate objects, such as toys, to show what the characters in a story event do (the treatment group), their recall of the story passage is better than children who only read the story without access to manipulating toys (the control group, Glenberg et al. 2004). This shows that manipulation is a beneficial *Active* strategy, assuming children do not further elaborate the stories with additional information. The control group clearly participated in a *Passive* only activity by just reading, so it is not surprising, based on ICAP's prediction, that enacting is better than reading only. With ICAP, we can now ask, are there much better *Constructive* strategies that can enhance reading, compared to enacting? Setting aside a consideration of the age-appropriateness of a strategy, one needs to ask whether examples such as posing questions (a *Constructive* strategy), either posing them to self (as in self-explaining, Chi, in press, or in reflection), posing them to others (Mestre, 2002), or posing them to the authors (Beck et al., 1997), would be a more effective learning strategy for learning than enacting? The same question can be asked about many other effective strategies. The point is that we can no longer claim in an absolute basis that a strategy is effective, without bracketing and comparing it with what other modes of strategies it is better than.

So, a theoretical value of the ICAP theory is that it can evaluate the effectiveness of a target strategy based on the mode it belongs, without needing to carry out an empirical study. It also implies caution in designing studies that compares a treatment with a *Passive* mode control condition. Being able to evaluate the relative effectiveness of strategies based on their mode also has the advantage of allowing instructors to know whether one strategy or activity can substitute for another. Finally, ICAP has practical value for informing instructors on how to design activities in various ICAP modes.

Introduction

Student-centered instruction or learning pedagogies promote teaching practices that stem from a constructivist view of learning. Although constructivism is an ill-defined concept, this view on learning starts from the idea that the learner is an active agent in the learning process, constructing one's own meaning while relating new information to prior knowledge. In other words, there is an emphasis on the construction of knowledge. Often, this knowledge construction process happens in a setting that involves peer-to-peer discussion and social interaction, although constructivist researchers acknowledge the importance of collaboration to a varying degree (Dunbar and Yadav, 2022; Loyens and Rikers, 2017). In addition, goal setting, plan making, and monitoring one's learning process (i.e., self-directed learning), are important foci of constructivist learning views (Loyens et al., 2008). Students need to "own" their learning processes and they can do this when they determine and accomplish learning goals. This process happens with the support of teachers as it is a common misconception that students will perform independently without external guidance. Instead, students should be scaffolded through the process from owning the learning question, problem or project, researching it, and sharing its outcomes. By varying the locus of perceived control, students maintain personal responsibility for learning (Hannafin et al., 2014; Lee and Hannafin, 2016). Finally, constructivist learning approaches usually use problems, cases, projects, and questions that are ill-structured (i.e., without a clear path to the solution or without a solution at all) and "authentic" (i.e., resemble real-life situations) in order to promote the application and transfer of knowledge (Loyens et al., 2021). A description of somebody who hurt herself and feels a throbbing pain around the wound a few days later can stimulate students to discuss topics such as the natural healing process of a wound, infection, and characteristics of inflammation (Dolmans et al., 1997). These single processes and features become more meaningful in the context of a story and it is believed that students construct personal meaning through working on these problems, questions, and projects (Hannafin et al., 2014).

A constructivist view of learning provides a common ground for student-centered instruction, as the principles of knowledge construction (i.e., connecting to students' prior knowledge), collaborative learning, autonomy, and working with realistic learning assignments (i.e., problems, projects, questions, cases) can be found in various forms of student-centered instruction (Loyens et al., 2021). In all formats, teachers create room for students to formulate and explore their answers to the posed question instead of providing students with a question and answer. This approach has crystallized into several teaching strategies that place an emphasis on the learner as an active agent in his or her learning process instead of the learner as a passive receiver of information. These instructional formats have been labeled 'student-centered' and employ classroom practices such as observations, generating questions, discovering gaps in one's knowledge base, and studying resources to try to overcome these gaps (Loyens and Rikers, 2017).

However, differences exist among several student-centered instructional methods. Barrows (1986) identified three variables that can vary in different student-centered approaches: the design and format of the problem, project, question or case; the degree to which learning is teacher centered or learning centered; and the sequence in which problems or tasks are offered and information is acquired. These varying factors have led to a variety of approaches, often lacking conceptual clarity, which has posed problems for practitioners and researchers in higher education (Gallagher and Savage, 2020). After all, effectiveness studies become difficult without a clear consensus on definitions and shared as well as different characteristics, as the risk for comparing apples and oranges becomes substantial. Given additional, more methodological issues associated with effectiveness research (e.g., lack of control group and lack of information on fidelity to the instructional approach; Granger et al., 2012), providing conceptual clarity seems to be a first step in the desired direction.

The present chapter aims to shed light on different student-centered approaches commonly found in the research literature. We successively discuss inquiry-based learning, problem-based learning, project-based learning, and case-based learning. Each of the instructional approaches is discussed in the light of the factors that Barrows (1986) put forward: 1) the design of the problem, project, case, question, 2) the level of student/teacher centeredness, and 3) the sequence in which information is acquired. In addition, we briefly describe two relatively newer methods that have emerged, team-based learning and challenge-based learning. These methods combine elements of specific student-centered formats and general beneficial learning strategies.

Inquiry-based learning (IBL)

Instruction based on inquiry emphasizes classroom practices that involve active participation of the learner as well as a prominent role for questions and issues generated by the learner. Generally stated, inquiry is based on a scientific investigation through classroom practices such as posing questions and it is aimed at knowledge acquisition and development (e.g., Blanchard et al., 2008). Because of this broad definition, IBL is often seen as an umbrella term for several student-centered classroom practices such as observations, generating questions, discussion, and self-study in the context of meaningful tasks (Loyens and Rikers, 2017; Tawfik et al., 2020). However, other researchers have described inquiry-based learning as a process related to scientific inquiry. In that case, IBL entails iterative cycles of hypothesis generation, experimentation (i.e., designing experiments suitable for generating or testing hypotheses), and evidence evaluation (i.e., critical assessment of the experimentation results) which lead to acceptance, rejection or revision of hypotheses (e.g., Lazonder and Harmsen, 2016). Indeed, Pedaste et al. (2015) define IBL as "a process of discovering new causal relations, with the learner formulating hypotheses and testing them by conducting experiments and/or making observations" (p. 47). Within this definition, inquiry is closely linked to reasoning and critical thinking and the empirical circle of scientific research, also referred as the *Scientific Inquiry Cycle* (SIC, Klahr and Dunbar, 1988; Lazonder and Harmsen, 2016). The SIC has been put forward as the core element in scientific reasoning (Schiefer et al., 2019). It is therefore not surprising that IBL is popular in science education (Loyens and Rikers, 2017). In a similar vein, IBL is often viewed as an approach to solving problems and involves the application of several problem-solving skills. Table 1 provides an overview of the different characteristics of IBL.

Table 1 IBL analyzed according to Barrows' (1986) factors.

Factor	Inquiry-based learning
1. Design of learning task	(Research) question E.g. "is sustainable agriculture good for the environment?"
2. Teacher versus student centered	Teacher = facilitator, providing guidance, having expert knowledge
3. Sequence of information acquisition	1) hypothesis generation 2) experimentation: Designing experiments suitable for generating or testing hypotheses 3) evidence evaluation: Critical assessment of the experimentation results, which lead to acceptance, rejection, or revision of hypotheses 4) scientific inquiry circle (SIC) can start again

Design of the learning question in IBL

In IBL, pupils formulate their own research question and design and conduct an investigation to answer the question (Windschitl, 2003). It can therefore be seen as a bottom-up approach (Van Uum et al., 2021). Pedaste et al. (2015) called the generation of research questions the “conceptualization” phase, which comes right after the initial “orientation” phase. While the orientation phase is focused on getting the learner started with a topic for investigation (i.e., exploring or observing a phenomenon to trigger interest and reading some theory in order to know the scientifically oriented questions related to the particular phenomenon), the process of generating research questions based on the stated problem constitutes the core of the conceptualization phase. The assignment of the learning task in IBL consists of activities such as ‘ask’, ‘question’, ‘ask questions’, ‘developing a question’, ‘initial inquiry question’, ‘generating a scientific question’, ‘set up of inquiry question’, ‘raising and revising questions’, and ‘decide my inquiry question’ (Pedaste et al., 2015, p. 52).

The level of student/teacher centeredness in IBL

The fact that pupils formulate their own research question, and design and conduct an investigation to answer the question, does not imply that teachers only observe their pupils. On the contrary, they have an important role in facilitating inquiry-based learning and scaffolding the knowledge and skills of their pupils (Van Uum et al., 2016, 2017). Indeed, Grant and Hill (2006) identified several factors influencing a student-centered learning environment such as IBL. One of these factors is the recognition and acceptance of new roles and responsibilities. This implies the acknowledgment that the teacher’s role is de-centered and hence becomes a facilitator of learning and a partner in learning with students. In addition, these authors mention that student-centered learning environments also demand flexibility from teachers to deal with potential ambiguity in students’ learning processes in IBL. Grant and Hill (2006) cited examples in this respect such as “The teacher is not the sole source of knowledge.” “Many lines of inquiry may be underway by students”, and “Student progress may be more difficult to discern” (p. 18). These examples clearly require a different role of the teacher. A recent study by Murphy et al. (2021) showed that some teachers appeared to see IBL as student-centered independent discovery, which created tension between loss of teacher control and the impact on student learning. The results of this study demonstrated that IBL was perceived as a challenge to the authority of the teacher. However, on the other hand, it was also acknowledged that the teacher’s role in managing dialogue in the classroom is paramount (Murphy et al., 2021). Indeed, the role of the guidance students receive during the IBL process has been directly linked to the effectiveness of IBL with “a reasonable degree of guidance being more effective than low guidance” (Lazonder and Harmsen, 2016, p. 683).

Sequence of information acquisition

As can be seen in Table 1, IBL follows a specific sequence of steps in the learning process. Generally speaking, the process starts with a question, formulation of hypothesis, experimentation, and evidence evaluation based on whether the hypothesis is rejected or accepted. Some researchers have added steps to this sequence of information acquisition such as the orientation phase discussed above (Pedaste et al., 2015). Some examples of IBL tasks were explained by Aditomo et al. (2013). In one of the IBL activities they described in the field of history, students had to decide on an individual research topic in local history, from which they developed research questions or aims, with assistance from the teacher to keep the research topic manageable and to find relevant resources. Based on both primary and secondary literature resources, they wrote a short history on their research project. An example in the domain of science (e.g., biomedicine) was that students were given three sets of DNA sequences and needed to use the computational tools and databases they had learnt about to discover the respective functions of the proteins. They were not told which tools to use, but the teacher did provide scaffolding if needed. Finally, an example put forward in the field of management was that students had to interview a family member, a flat-mate, a friend, or a colleague or boss using a particular theory of motivation (i.e., goal-setting, expectancy or equity theories), and analyze their current levels of motivation. Using the same theory, students had to identify areas for improving their motivation (Aditomo et al., 2013). In all examples, the starting point was a (research) question such as “By which theory could one’s current level of motivation best be explained and how could it be improved?”, followed by hypothesis generation, experimentation, and evidence evaluation.

Problem-based learning (PBL)

The central feature of PBL is that the learning process starts with a complex, ill-structured problem that describes one or more observable phenomena or events (Schmidt, 1983). As is true for all formats of student-centered instruction, a plethora of definitions and formats of PBL exist. Nevertheless, Barrows (1996) defined six core characteristics of PBL. The first characteristic is that learning needs to be student-centered. Second, learning has to occur in small student groups under the guidance of a teacher, a so-called tutor. The third characteristic refers to the tutor as a facilitator or guide instead of a provider of knowledge. Fourth, so-called “authentic” (i.e., relating to real life) problems are primarily encountered in the learning sequence before any preparation or study has occurred. Fifth, the problems are used as a trigger for students’ prior knowledge before any other curriculum input, which leads to the discovery of knowledge gaps. Finally, these knowledge gaps are overcome through self-directed learning, which requires sufficient time for self-study (Schmidt et al., 2009).

Besides the core characteristics, shared characteristics can also be found in terms of the process, which always starts with a problem that is discussed in a group meeting. Issues that need further clarification and study are collaboratively agreed on and formulated in the form of questions (i.e., learning issues). Next, students individually try to find answers to these learning issues during a period of self-directed, individual study that usually lasts a couple of days. Finally, students return to their groups and discuss the answers found (Wijnia et al., 2019), critically evaluating all students' findings and weighing the evidence found for their answers to the learning issues (Loyens et al., 2022). Table 2 provides an overview of the different characteristics of PBL.

Design of the learning task in PBL

As mentioned earlier, the problem is the first input that PBL students encounter. On some occasions (e.g., in medical education), these problems originate from professional practice; in other cases, they tackle problems or events typical for a particular domain of study (Barrows, 1996; Norman and Schmidt, 1992; Schmidt et al., 2007). Since these problems need to be understood in terms of their underlying theoretical explanations, they need to have several characteristics that ensure sufficient scaffolding for the brainstorm, the formulation of learning issues, and students' self-study activities. Several researchers have proposed central features for problem construction in PBL (Dolmans et al., 1997; Otting and Zwaal, 2006). All taxonomies can be narrowed down to five "rules" for effective problems. PBL problems need 1) to build on prior knowledge, 2) elicit discussion, 3) stimulate SDL, 4) encourage knowledge integration and transfer, and finally, 5) they need to be relevant for students' future profession (Loyens et al., 2012).

Building on prior knowledge

Research in cognitive psychology has demonstrated that prior knowledge influences the quantity and quality of new knowledge (e.g., Anderson, 1990). Students need to be acquainted with at least part of the knowledge necessary to solve the problem. If not, the brainstorm is impossible. Problems that are too difficult will lead to frustration and a decrease in motivation. Problems that are too easy will be perceived as boring and insufficiently challenging and might be more effective for individual learning than for collaborative learning (Kirschner et al., 2009). Therefore, problem complexity needs to be tuned to students' prior knowledge (Otting and Zwaal, 2006). An implication of this problem characteristic is that a PBL curriculum needs to have a balanced structure. A specific problem about diabetes, for example, can only be presented to medical students after they have gained knowledge about the anatomy and physiology of the human body (Dolmans et al., 1997).

Eliciting discussion

A problem not only needs to build on students' prior knowledge, it also has to make sure it can retrieve this knowledge and subsequently elicit discussion. The retrieval of prior knowledge is crucial since new information can then be related to it. A problem can

Table 2 PBL analyzed according to Barrows' (1986) factors.

Factor	Problem-based learning
1. Design of learning task	Real-life problem E.g., "Jan and Erik, identical twins, lost their parents at the age of 7 from a car accident. Jan was fostered in the (3 children) family of a contract-laborer. Erik was fostered by the (also 3 children) family of a scientist. At the age of 6, both Jan and Erik were psychologically evaluated. Jan's IQ was measured as 111, that of Erik was 108. At the age of 12, both boys were evaluated again. Jan's IQ was now 93, and that of Erik 123. Explain the difference in the results" (Schmidt and Bouhuijs, 1981, p. 6).
2. Teacher versus student centered	Teacher = facilitator and stimulator of group discussion, providing guidance, ideally possessing subject matter expertise, cognitive congruence, and social congruence (Schmidt and Moust, 1995)
3. Sequence of information acquisition	1. Pre-discussion of a complex problem (i.e., <i>brainstorm</i>) in a group meeting. This pre-discussion of the problem ends with a collaborative formulation of learning issues (e.g., what are possible treatments for dyslexia?) 2. Individual self-directed learning activities (i.e., selecting and studying literature resources) 3. Reporting phase: Sharing and critically evaluating the literature findings in the second group meeting (Wijnia et al., 2019)

elicit discussion when it contains certain cues such as opposite views, so that students can generate arguments for and against each view and discuss which view is best. Most suitable in this respect are so-called *ill-structured* or *ill-defined problems*, because these problems can have multiple solutions and can be solved in multiple ways (Otting and Zwaal, 2006). Furthermore, ill-structured problems better represent problems that one can encounter in daily life and are hence more realistic (Loyens et al., 2012).

Stimulating self-directed learning

Problems need to lead to the formulation of learning issues that guide students' self-study activities (e.g., Hmelo-Silver, 2004), since PBL students determine themselves what they find relevant for their learning based on the learning issues (Barrows, 1996). The self-study activities to answer the learning issues are assumed to prepare students for autonomous problem solving later in life (Dolmans et al., 1997). An ill-structured problem can stimulate the formulation of learning issues and further self-directed learning because of the multiple solutions as described earlier. This can generate discussion in the tutorial group but can also cause cognitive conflict within the student (Dolmans et al., 2001; Loyens et al., 2015).

Encouraging knowledge integration and transfer

Problems need to encourage students to integrate their acquired knowledge so that they can apply this information in a subsequent, new situation. In other words, a problem needs to establish transfer of knowledge. To accomplish this, information needs to be presented in a broad context so students can better understand the purpose of the single problem elements. A description of somebody who hurt herself and feels a throbbing pain around the wound a few days later can stimulate students to discuss topics such as the natural healing process of a wound, infection, and characteristics of inflammation (Dolmans et al., 1997). These single processes and features become meaningful in the context of a story. Knowledge acquired in a meaningful context becomes more easily accessible, promoting transfer (Otting and Zwaal, 2006; Van der Vleuten et al., 2000).

Relevance for future profession

Finally, PBL problems are, preferably, relevant for students' future profession. Such problems are considered to be more motivating and lively for students (Loyens et al., 2008; Otting and Zwaal, 2006). Furthermore, they are thought to narrow the bridge between the learning situation and praxis, since they become more similar (Van der Vleuten et al., 2000). Presenting medical students with a patient's file is a good example in this respect.

The problem example presented in Table 2 about IQ and the nature-nurture debate can be presented to first-year PBL psychology students after they have studied the topic of intelligence. In this way it can build on students' prior knowledge since students typically first learn about theories of intelligence as well as the development of intelligence before tackling the nature-nurture debate. The problem deals with an important topic within psychology, intelligence and the nature-nurture debate, and is hence relevant for some of the students' future profession as a school, clinical, or educational psychologist. It contains different, relevant elements about DNA (i.e., the fact that Erik and Jan are identical twins), the families in which Jan and Erik were brought up, their IQ scores at the age of six and at the age of 12 etc., that are important for understanding the problem and that need to be integrated. This leads to a discussion about the difference in IQ scores between the age of six and 12 and most importantly, how this can be explained. Multiple options are possible and students need to unravel these options during self-study based on the formulated learning issues (e.g., "How does IQ develop?" "What is the role of genetics and environment in (the development of) IQ?").

The level of student/teacher centeredness in PBL

As mentioned, the starting point of the learning process in PBL is the problem. Problems are designed by instructors, which might be considered more teacher-centered compared to, for example, project-based learning (PjBL, see below) where students can often choose their own project to work on. However, Barrows (1996) identified "the teacher as facilitator or guide" as a core characteristic of PBL with the teacher's role being significantly different compared to that in lecture-based curricula. The student-centeredness also lies in the fact that, in the PBL process, students determine themselves what they find relevant for their learning based on the learning issues they collaboratively formulate (Barrows, 1996). The role of the tutor in PBL is to facilitate and stimulate group discussion, make sure the problem content is considered in-depth, and evaluate the group members' contributions to addressing the problems (Barrows, 1985; Loyens et al., 2012; Schmidt et al., 2007). Hence, whenever needed, the tutor is expected to ask open-ended, metacognitive questions such as "Explain in your own words what this article says about the learning issue?" when students are primarily summarizing instead of discussing or "How does this article differ from the other?" or "What do you think?" By asking such questions and catalyzing group progress, the tutor helps support knowledge building. Ideally, tutors' interventions diminish over time as students become more knowledgeable with the PBL process on the one hand and become more self-directed on the other hand, although empirical evidence on this issue is scarce and not decisive (Hmelo-Silver and Barrows, 2008).

In terms of tutor characteristics, Schmidt and Moust (1995) put forward the idea that effective tutors need cognitive congruence, social congruence, and expertise. Cognitive and social congruence emphasize the personal qualities of the tutor. *Cognitive congruence* refers to the ability to "frame his or her contributions in a language that is adapted to the level of the students" (Schmidt and Moust, 1995, p.709), whereas *social congruence* implies the tutor's willingness to be involved with the students' life and learning. A tutor also needs a suitable knowledge base for the topic under study, also referred to as *subject-matter expertise* (Schmidt and Moust, 1995, 2000). A review of research on the role of tutors in PBL supported the claim that both congruence and expertise are needed (Dolmans et al., 2002) as does a study in which good tutors were described by students as those who know when and how to intervene

without dominating (Maudsley et al., 2008). Another study on students' perceptions of the tutor showed that students saw effective tutoring as being equivalent to stimulating active learning. Distinctions between poor and excellent tutors came down to three dimensions in the eyes of students: degree of direction (i.e., not too directive, but not too passive either), content knowledge, and adequate evaluations of both content and process (Dolmans et al., 2006).

Sequence of information acquisition in PBL

Wijnia et al. (2019) highlighted that PBL as a process consists of three separate stages: an initial discussion phase, a self-study phase, and a reporting stage. Firstly, students are given a meaningful problem that describes an observable phenomenon or event. During the first stage, prior knowledge of the problem is important, as students come up with theories to explain the problem. As mentioned, students brainstorm about the problem before they receive other curriculum input and, therefore, they need to rely on their prior knowledge. Together, students try to construct understanding of the problem and discuss possible explanations or solutions. Because their knowledge is limited and insufficient, learning issues (formulated as questions) to guide students' research and study are formulated for further self-study. All of this is undertaken in a class discussion of five to 12 students.

During the second stage, students consult learning resources to gain knowledge about the problem and to answer the learning issues. These resources can be selected by the students, the tutor, or a combination of both (Wijnia et al., 2019). Next to selecting relevant literature about the topic to be studied, students need to plan their study activities to optimally prepare themselves for the next tutorial group meeting, assess whether their self-study activities were sufficient to fully understand the subject matter introduced in the problem, etc. (Loyens et al., 2008).

In the final stage, students reconvene under the guidance of their tutor to share and evaluate their findings critically and elaborate on their newly acquired knowledge. This knowledge is then applied to the problem in order to identify solutions or explanations (Loyens et al., 2022; Loyens and Rikers, 2017; Wijnia et al., 2019).

In general, these stages can be identified in the PBL process, although the specific steps that are to be followed can differ (for an overview of the different formats of the PBL process, see Wijnia et al., 2019).

Project-based learning (PjBL)

The central characteristic of project-based learning or project-centered learning (PjBL) is the project, through which students learn central concepts and principles of a discipline (Blumenfeld et al., 1991). During collaborative and problem-solving activities, students acquire new domain-specific knowledge and thinking skills useful in solving real-world problems, with a facilitating role for instructors (Chiu, 2020). Projects last for a considerable period of time (Helle et al., 2006).

Also, in PjBL, different implementations can be found, but most formats start with a driving question or problem and seem to incorporate the following features (Krajcik, 2015; Thomas, 2000): (a) the projects for which the students seek solutions or clarifications are relevant to learners' lives; (b) PjBL involves planning and performing investigations to answer questions; (c) students collaborate with other students, teachers, and members of society; and (d) PjBL is centered around producing artifacts. In addition, often technology tools are used when appropriate (Krajcik, 2015). A distinction should be made between regular projects used in education and in PjBL. The Buck Institute for Education makes this distinction:

We find it helpful to distinguish a "dessert project" – a short, intellectually-light project served up after the teacher covers the content of a unit in the usual way – from a "main course" project, in which the project is the unit. In Project Based Learning, the project is the vehicle for teaching the important knowledge and skills students need to learn. The project contains and frames curriculum and instruction

Buck Institute for Education (n.d.)

Through working on a project in PBL, skills such as critical thinking, problem solving, collaboration, and various forms of communication are believed to be fostered (Buck Institute for Education, n.d.). In sum, students are involved in a series of collaborative inquiry activities that help them acquire new, domain-specific knowledge and thinking skills useful in solving real-world problems (Saad and Zainudin, 2022). The PjBL end products are believed to reflect a learner's knowledge in information search, knowledge related to the project's topic, and metacognitive knowledge (Grant and Branch, 2005). Table 3 provides an overview of the different characteristics of PjBL.

Design of the learning task in PjBL

A project can be a problem to solve, a phenomenon to investigate, a model to design, or a decision to make, and usually starts with a driving question. An example from elementary school is: "How can we build a tiny house, taking into consideration budget, location, and personal preferences?" (Buck Institute for Education, n.d.).

Specific end products need to be reached, and these are clearly defined, while the processes to get to the end products can vary. The end products (e.g., a website, presentation, report) serve as the basis for discussion, feedback, and revision (Blumenfeld et al., 1991; Helle et al., 2006; Nurbekova et al., 2020; Tal et al., 2006).

Table 3 PjBL analyzed according to Barrows' (1986) factors.

Factor	Project-based learning
1. Design of learning task	Project that starts with a driving question E.g., "how can we build a tiny house, taking into consideration budget, location, and personal preferences?" (Buck Institute for education, n.d.)
2. Teacher versus student centered	Teacher = facilitator, helps with framing and structuring the projects, monitors the development of the end product, and assesses what students have learned
3. Sequence of information acquisition	The process starts with a driving question. The process to reach the end product (e.g., website, microbot, tiny house) may vary, but stages can often be distinguished (i.e., project organization, project implementation, and project evaluation; Nurbekova et al., 2020)

The level of student/teacher centeredness in PjBL

The projects are student-driven, which means that students have a significant degree of control of the project they will work on and what they will do in the project. This is in contrast to PBL in which the problems are designed by the instructor. The role of the instructor consists of facilitating the project. That is, the instructor helps with framing and structuring the projects, monitors the development of the end product, and assesses what students have learned (Chiu, 2020; David, 2008; Helle et al., 2006). An instructor can also choose to include experts and clients. For example, in the tiny house example for elementary school, part of the project consisted of interviewing clients and making an inventory of their wishes for the tiny house. In these interviews, learners needed to obtain crucial information from their "clients" such as the budget available and minimum square feet for their tiny house. The expert in this project was a structural engineer who demonstrated and explained a blueprint of a tiny house.

In sum, the projects in PBL are student-centered and the teacher takes on a facilitating role. In this facilitation, the teacher can bring in external persons and experts to fulfill a specific role in the project (Buck Institute for Education, n.d.).

Sequence of information acquisition in PjBL

As the project is key in PjBL, specific end products need to be reached. While the end products are clearly defined (e.g., develop a microrobot, design a specific plan, build a tiny house for a client), the processes to reach the end products can vary. In some projects, the stages of project organization, implementation, and evaluation can be distinguished (Nurbekova et al., 2020). For project organization, activities at the conceptual stage take place (e.g., formation of the project team, project selection based on the driving question, problem definition, objective of the project) as well as team building with function distribution (e.g., defining project tasks and exploring resource capabilities). During project implementation, the actual development of the product takes place (e.g., designing and programming a microrobot) as well as a first testing phase (e.g., testing and debugging the software and hardware of a microrobot). During the subsequent project evaluation phase, the project is presented (e.g., the project presentation is prepared and the "public defense" of the project takes place) and finally, the work performed is analyzed (Are the goals achieved, what went well, what went less well and why? etc.; Nurbekova et al., 2020).

Case-based learning (CBL)

In line with the previously discussed student-centered formats, there is also no consensus as to the definition of case-based learning (CBL), also referred to as case study teaching and case method learning. Nevertheless, it is considered a form of student-centered instruction and fits on the continuum between structured and guided learning (Thistlethwaite et al., 2012).

The goal of CBL is to prepare students for practice through the use of authentic cases and it centers instruction around those cases (Tawfik et al., 2020). It links theory to practice, through the application of knowledge to the cases, using inquiry-based learning methods (Thistlethwaite et al., 2012). CBL is used in many business schools, law curricula, and in medical education (Tawfik et al., 2020; Thistlethwaite et al., 2012). In contrast to other student-centered strategies, CBL focuses more on an instructor-driven discussion of the case with the student (Williams, 1992). Table 4 provides an overview of the different characteristics of CBL.

Design of the learning task in CBL

CBL is a form of collaborative learning where learners are presented with a case. For example, in a teacher education course, students can be presented with a case on classroom management in which the teacher wants to change the arrangement of children's desks because two boys are constantly talking and interrupting the class instruction. However, one of the two boys seems to have few

Table 4 CBL analyzed according to Barrows' (1986) factors.

Factor	Case-based learning
1. Design of learning task	The learning task starts with a case that students prepare. E.g., case on classroom management for students to prepare. "The teacher wants to change the arrangement of children's desks because two boys are constantly talking and interrupting the class instruction"
2. Teacher versus student centered	Teacher = facilitator, but has a more prominent role in the discussion of the cases. Whereas in PBL, the facilitator can remain silent when the group discussion is going well, in CBL the group discussion is led by the teacher.
3. Sequence of information acquisition	1. Students prepare the case before they come to class, using prior knowledge but also literature resources. For example, for cases in law school, students will search legal dictionaries, encyclopedias, textbooks, statutes, and treatises to help them understand the case (Williams, 1992). 2. The teacher poses a number of questions to the group of students related to the case. For example, in law education, the teacher may question the decision made by the court described in the case. "The discussion session serves as the venue for students to collaboratively apply learned principles and data analyses and evaluate the usefulness of various strategies to achieve optimal resolutions of the case" (Bowe et al., 2009, p. 835, p. 835) 3. Optional: The teacher presents a series of related hypothetical cases that represent variations or perturbations of the original case.

friends and is experiencing problems adjusting to school, and the boy next to him seems to be the only one he is close with (Choi and Lee, 2009, p. 104). Cases are similar to problems in PBL. However, in Barrows' terms (1986), the sequence of the problem and gathered information is different. In PBL, the problem is the starting point. In CBL, students need to prepare in advance for the group session and can ask questions during the session, when the case is discussed under the guidance of a facilitator (Srinivasan et al., 2007; Williams, 2005). Therefore, CBL is sometimes considered as a special form of PBL. Both PBL and CBL share a focus on acquiring new knowledge (Aditomo et al., 2013). The overlap between PBL and CBL can also be seen in the characteristics of the learning task, which share significant overlap: cases need to be "authentic" and typical (i.e., based on real-life events or patients or situations to enhance the relevance of the subject matter by focusing on the actual performance of professionals.), stimulate interest, tell a story, promote decision making, and be aligned with defined learning outcomes. Cases can be real (e.g., real patients in health professional education), simulated, virtual, or text-based (Thistlethwaite et al., 2012). Williams (1992) added in this respect that the cases used in CBL reflect real cases, but these cases often contain less complexity and do not contain irrelevant details.

The level of student/teacher centeredness in CBL

CBL focuses more on an instructor-driven discussion of the case with the student. Also, students need to prepare the case at home and, whereas learning issues/questions are collaboratively decided upon in PBL, the learning issues are determined by the teacher in CBL (Thistlethwaite et al., 2012). The teacher also has a more prominent role in the group discussion. As noted in Table 4, whereas in PBL the teacher (i.e., tutor) can remain relatively silent during the group discussion when the students are doing a good job and little 'steering' is necessary, the situation is different in CBL, where the teacher leads the discussion of the case.

Even though the teacher plays a key role in facilitating the discussion in CBL, this method can still be considered student-centered. As Bowe et al. (2009) stated: "The Case Method Teaching format encourages students to articulate their perspectives and propose problem-solving strategies. It also provides the faculty valuable insight into the students' understanding of key concepts and their ability to effectively apply them" (p. 835).

Some researchers have argued that CBL is more structured than PBL, but that is to a large extent dependent on the method used for the learning process, as PBL formats can also employ structured methods to guide the group discussion (Wijnia et al., 2019).

Sequence of information acquisition in CBL

Typically, CBL takes place in face-to-face groups but may also take place online. Students review cases prior to sessions in order to be able to discuss them in groups. By preparing the case independently at home, students can identify the key issues of the case and

study additional resources (see [Table 4](#) for examples). The preparation at home is crucial to ensure a thorough and in-depth discussion of the case in the classroom. After preparing the case at home, students return to their classes where the teacher starts a facilitated discussion with trigger questions about the case ([Bowe et al., 2009](#)). As an optional third step, the teacher can present related hypothetical cases that represent variations of the original case, which allow students to apply their newly learned knowledge to a new and different case. Practically, a teacher can introduce a case in a lecture and let students prepare the case independently. The lecture is then followed by a group session in which the case is analyzed in depth. Typically, students have little work after the session in which the case is discussed ([Bowe et al., 2009](#)).

Acquaintances of the student-centered family: team-based and challenge-based learning

As mentioned, the lack of clear definitions makes it difficult to distinguish the different student-centered formats. Concepts are often confused (e.g., problem- and project-based learning and problem- and case-based learning), or incorrectly explained (e.g., calling a method PBL when the problem is not the starting point of the learning process). What also adds to the difficulty in reaching conceptual clarity is the fact that new methods have emerged throughout the years, sometimes combining elements of specific student-centered formats and general beneficial learning strategies.

Team-based learning

One such example is Team-based learning (TBL), which could be considered a PBL variant since students also work on problems in teams. It is similar to CBL in that students have to prepare before coming to class. One could argue that TBL overcomes some of the problems put forward with respect to PBL. For example, an often-heard criticism of PBL concerns the facilities (small rooms are needed to host the tutorial group discussions of 10–12 students each) and associated costs (all groups need a tutor to facilitate the PBL discussion, requiring a large number of tutors; [Loyens et al., 2012](#)). In TBL, one teacher facilitates various small teams, sometimes 20 or even more ([Dolmans et al., 2015](#)). Students gather in teams and they are all present in the same large room in TBL. TBL also makes use of the beneficial learning strategy of testing. Practice testing one's knowledge has been shown to be a very effective learning strategy ([Dunlosky et al., 2013](#)). Before group sessions, students have to complete a mandatory reading assignment and their individual knowledge of the materials is assessed in a multiple-choice test. In the teams, students discuss their individual answers to the exact same test items with each other to reach team consensus and receive immediate feedback on the team answers ([Haidet et al., 2012](#); [Dolmans et al., 2015](#)). This test provides the teacher with valuable information about difficult concepts for students, so that extra attention can be paid to the clarification of those concepts. Subsequently, students work in the same teams to resolve professionally relevant, challenging, and complex problems. After teams have worked on the problem, they present their solutions in plenary to the other teams. Solutions to problems are exchanged and challenged through discussion, facilitated by the teacher ([Dolmans et al., 2015](#)). Often experts are invited to attend these plenary sessions. In terms of the level of student/teacher centeredness, one could say that TBL is more structured regarding the teams, the pre-activity testing, and the formation of the problems ([Davis, 2017](#)). In addition, there is a strong focus of TBL on collaboration and the acquisition of teamwork skills ([Dolmans et al., 2015](#)).

Challenge-based learning (ChBL)

ChBL is another approach that is identified as a student-centered format with links to the above-mentioned approaches. In ChBL, “students collaborate with academia, industry and extra-academic actors to solve real-world challenges through creative and authentic experience” ([Gallager and Savage, 2020](#), p. 2–3). Hence, stakeholders from multiple settings are used in ChBL to support students. This aspect is different from other formats, where teachers usually act as facilitators (see [Tables 1–4](#)), with the exception of PjBL, where extra-academic actors can also be invited to the classroom. [Gallager and Savage \(2000\)](#) reviewed 100 articles to discover the key principles of ChBL. They found that ChBL is usually focused on themes of global importance such as sustainability and other real-world challenges. The solution of, or decision on, the challenge often requires input from multiple disciplines, creativity and innovation, and the use of technology. Depending on the methodology followed, the challenges in ChBL can be either defined by the students or by the teachers. Unlike PjBL, the focus is not just on the final product but also on the process, which is viewed as being as important ([Gallager and Savage, 2000](#)).

Directions for future research

This chapter aimed to achieve conceptual clarity on several distinct student-centered methods. Although significant overlap can be observed in IBL, PBL, PjBL, and CBL, they all have their unique features. These unique features make it paramount to include definitions as well as details on the procedures and methodology. Both are of key importance in research articles. Only by doing so, will it become possible for researchers to fully understand student-centered formats and conduct reviews and meta-analyses. In a recent review on critical thinking in PBL and PjBL, the most prevalent reason for exclusion of research articles was a lack of a clear definition and/or description of the methodology ([Loyens et al., 2022](#)).

Although this chapter dealt with the conceptualizations of student-centered instruction, an inevitable follow-up question is how effective these methods are in fostering learning. The majority of studies deal with experiences of teachers and students with these methods, while there is a paucity of controlled effect studies (Granger et al., 2012; Loyens et al., 2012). Effect studies should not serve the sole purpose of answering questions such as “Which method is better than the other?”; nonetheless, the effects of instructional formats can only be established with a comparable control group. Whereas the effects of student-centered formats on knowledge acquisition have been well documented (e.g., Chen and Yang, 2019; Lazonder and Harmsen, 2016; Walker and Leary, 2009), the effects on skill acquisition have been less frequently studied. Only with well-conducted and well-documented research, can we combine the best of all worlds and advance the use of student-centered approaches in classrooms.

Introduction

In 2010, two of the authors of this current chapter wrote an article on Universal Design for Learning (UDL) for the third edition of the *International encyclopedia of education* (Rose and Gravel, 2010). In that chapter, we introduced UDL, a framework for teaching and learning that guides the design of accessible, inclusive, and challenging learning environments (Rose and Meyer, 2002). At the time, the UDL field was just in its first decade, and we framed UDL as “still in the very early stages of development” (p. 124). We described that while UDL was gaining traction at the policy level, “most educators do not really know what UDL means” (p. 119). Thus, the goal for that 2010 chapter was “to clarify what is meant by UDL and especially to provide the evidentiary basis for its principles and a review of its guidelines” (p. 119).

Now more than 11 years later, we have the opportunity to contribute once again to the *International encyclopedia of education*, and the field of UDL has dramatically changed. UDL has now entered into its third decade and has gained remarkable momentum within individual classrooms, school systems, and international educational initiatives. Schools and institutions of higher education throughout the U.S. and abroad are embarking on UDL initiatives in order to design inclusive learning environments that reduce barriers and support learners to thrive. For example, Bartholomew Consolidated School Corporation (BCSC) in Columbus, Indiana, USA, implemented a district-wide UDL initiative more than a decade ago, and UDL has become an overarching framework for schools across the district (BCSC, 2021). Further, institutions of higher education such as Boston College, Goodwin College, and the California State University System have developed UDL initiatives to promote the application of UDL to course design (UDL on Campus, 2021). There has also been remarkable growth in professional learning around UDL. In the past year alone, CAST’s professional learning team has collaborated with more than 4000 educators across 44 states and 25 countries. Finally, UDL has taken hold at the national policy level. In the US, for example, UDL has been defined and endorsed in the Every Student Succeeds Act (ESSA) of 2016 and incorporated into the Strengthening Career and Technical Education for the 21st Century Act of 2018 (CAST, 2021). Further, UDL has been emphasized in two recent versions of the National Education Technology Plan, a policy document that articulates the vision of technology in US schools (CAST, 2021).

UDL has been shaped by various stakeholders in the educational community, including practitioners, researchers, and developers of educational materials such as digital curriculum and instructional technology tools. Established in 2011, the UDL Implementation and Research Network (UDL-IRN), a grassroots organization, was instrumental in bringing together stakeholders and fostering ongoing dialog, cross-pollination of perspectives, and expertise around UDL (UDL-IRN, 2022). In the past decade, members of the UDL-IRN have collaborated to develop various tools and resources and disseminate information including white papers, databases of UDL studies, and tools for designing and reporting on UDL (see udl-irn.org/). Further, more researchers are exploring UDL through lenses such as equity, instructional design, learning technologies, and teacher education, with major educational journals such as the *Harvard Educational Review* dedicating a forum (Alim et al., 2017) and *Remedial and Special Education* dedicating a special issue (King-Sears, 2020) to the topic. Finally, UDL has gained a marked presence in social media and a weekly #UDLchat on Twitter which attracts a dedicated number of followers. Thus, UDL today represents a framework that has matured through the integration of ideas, perspectives, applications, and research by the educational community itself.

In this chapter, we trace the maturation and development of the UDL framework in the past decade. UDL today has come to represent both a set of values around inclusive education and an instructional design framework that can be applied to the design and development of curriculum and instruction. At a macro level, UDL is an orientation toward teaching and learning—a framework that has the potential to prompt practitioners to uncover and wrestle with their preconceived attitudes and beliefs. At a practical level, UDL is a way to consider educational practices and develop flexible and engaging curricula. In this chapter, we address these two aspects of UDL and also share a vision for the future.

What is UDL?

Universal Design for Learning (UDL) offers a framework for teaching and learning that guides the design of accessible and challenging learning environments (CAST, 2021a). The UDL framework was first developed at CAST (formerly known as Center for Applied Special Technology), a not-for-profit research and development organization formed in 1984 by a group of about 20 clinicians (mostly neuropsychologists) and educators (mostly teachers and evaluators of children with disabilities) who worked at the Medical and Educational Evaluation Center within a children's hospital near Boston, Massachusetts. The original focus of that group was on identifying how new and emerging technologies might be helpful for the children who were diagnosed as having disabilities that interfered with their learning in traditional schools. Eventually that work led to a significantly different mission: identifying and expanding the ways that new learning technologies could reduce the barriers and impediments that many children faced in traditional schools. Eventually CAST left the hospital setting—where the focus was on “fixing” children who were considered “deficient” in some way—and launched as a separate organization whose focus was on “fixing” or transforming the curriculum to support and embrace the natural variability of learners.

Eventually CAST's approach attracted a variety of educators, designers, technology developers, researchers, and learning scientists. Together that group began to formalize an approach to educational re-design that had much in common with the Universal Design movement in architecture, and began calling the approach Universal Design for Learning. Given the focus on learning rather than physical structures, CAST developed a foundational framework and guidelines that were based in the learning sciences, particularly in cognitive and affective neuroscience. That work had roots in classical developmental psychology and neurology (e.g., Piaget, 1952; Vygotsky, 1978; Wood et al., 1976; Luria, 1976), but also in contemporary cognitive and affective neuroscience. Referencing Luria's original formulation and many others who followed, the UDL framework is based on the foundation of the three main divisions of the brain: the affective network, responsible for emotional functioning; the recognition network, responsible for perceptual and pattern recognition functioning; and the strategic network, responsible for motor and executive functioning (Meyer et al., 2014). These three brain networks provide the foundation for the three principles of UDL: provide *multiple means of engagement* to motivate learners; provide *multiple means of representation* to ensure that learners can access information; and provide *multiple means of action and expression* to support learners to act on and express what they know (Meyer et al., 2014).

CAST's *UDL Guidelines*, which are available at udlguidelines.cast.org (CAST, 2018b), are a tool to support stakeholders in applying the UDL principles to practice. They too are based on the basic structure of the brain, in this case, the “hierarchical” structure of each of the three brain systems, from the primary sensory, motor, and limbic cortex up through the “tertiary” prefrontal cortex where affective, executive, and cognitive functions merge. More informally, many describe the three resulting rows in the guidelines as the following: The “access” row offers guidelines to ensure that learners have access to the learning goal by recruiting interest and by offering options for perception and physical action; the “build” row offers guidelines to develop effort and persistence, language and symbols, and expression and communication; and the “internalize” row represents the guidelines to develop self-regulation, comprehension, and executive function (CAST, 2021b). The guidelines culminate to the ultimate goal of supporting the development of “expert learners” who “are, each in their own way, resourceful and knowledgeable; strategic and goal-directed; purposeful and motivated” (Rose and Gravel, 2013, pp. 82–84).

UDL as an orientation

Over the past three decades, UDL has developed as a framework for reflecting on orientations and commitments toward teaching and learning. Many stakeholders within the UDL community—including preK–12 educators, faculty members in higher education, curriculum developers, researchers, parents, and others who apply UDL to the design learning environments—have leveraged UDL as a tool to begin to explore the attitudes and beliefs they bring to their practice. Thus, UDL has matured as a framework that can potentially prompt practitioners to uncover and consider their preconceived values, supporting practitioners to wrestle with their orientations toward learner variability, their framing of barriers to learning, and their beliefs about the capabilities of all learners.

Embracing learner variability

UDL encourages educators to examine their beliefs with regard to individual differences among learners. The framework is rooted in the notion of learner variability—the idea that learners are highly variable in the ways that they learn. Meyer et al. (2014) emphasize that “individual brains are remarkably distinctive in their anatomy, chemistry, and physiology” and that “like each person's

fingerprints, every brain is unique” (p. 49). This notion stands in stark contrast to the tendency to design for the “mythical average learner” that is deeply entrenched across the education system in the United States—and in other countries as well.

The UDL framework’s rejection of the “average learner” is closely aligned to the social model of disability, a model that positions normalcy as a social construct and upholds disability as a result of the interaction between the individual and the environment. In contrast to the medical model that interprets disability as a deficit that must be fixed, the social model frames disability as a natural variation of the human experience (Baglieri and Lavani, 2019; Shakespeare, 2010). Similarly, the UDL framework positions disability—and individual differences among learners more broadly—as a natural and inevitable form of human variation. Thus, UDL has the promise to prompt educators to examine their beliefs with regard to the meaning of “average” and “normal” and to embrace the natural variability of learners.

Reframing of barriers to learning and relocating the “problem” to be fixed

Identifying and reducing barriers to learning is a central tenet of UDL. Oftentimes, educators are socialized into practices and deficit orientations that locate barriers within learners themselves. For example, an educator may believe that a learner is unable to understand the plot of a story because the themes are too complex, or a learner is unable to complete a long-term project given their struggle to stay organized. The UDL framework supports educators to relocate the “problem” from within the individual learner to within the design of the learning opportunity, emphasizing that it is the curriculum rather than the learner that needs to be “fixed” (Meyer and Rose, 2005). UDL prompts educators to ask: What barriers stand in the way of the learning goal? How might I apply UDL to reduce these barriers and increase access to the goal? For example, if the goal is understanding plot, the UDL framework supports educators to consider options for reducing barriers to the text, including text-to-speech, audiobook versions, and graphic organizers to uncover plot structure. If the goal is to complete a long-term assignment, UDL prompts educators to consider options for supporting organization and executive function such as developing short-term goals, creating checklists, and engaging in consistent check-ins with peers.

This relocation of the “problem” can be a powerful way to support educators to begin to reframe their understandings and beliefs with regard to barriers in their classrooms. UDL encourages educators to approach challenges through a mindset that shifts away from identifying barriers within individual learners and instead focuses on ways to reduce barriers in the learning environment through proactive design. (See [Box 1](#) for examples).

Reconsidering beliefs about the capabilities of all learners

The UDL framework has also developed to be a potentially powerful tool that educators can use to examine their expectations and reimagine the capabilities of all learners. Far too often, educators are socialized into entrenched cultures of low expectations (Baglieri et al., 2011; Causton-Theoharis et al., 2011; Gartner and Lipsky, 1987; Hehir, 2002). UDL provides a lens for educators to examine and confront limiting beliefs.

As noted above, UDL is focused on the goal of supporting learners to develop as “expert learners” (Rose and Gravel, 2013). Instead of focusing on basic facts and rote memorization, UDL emphasizes the importance of designing learning goals that engage learners in meaningful ways of thinking and doing. This emphasis on the goal prompts educators to interrogate the nature of their learning goals and to explore the values and beliefs that undergird them. Is the goal rigorous? Is the goal authentic to learners? Do educators believe that all learners can engage in these rigorous and authentic goals? UDL encourages educators to begin examining these challenging questions and to reconsider the kinds of goals that they set for their learners—as well as the kinds of goals they support learners to set for themselves.

Box 1 Teacher perspectives of a UDL mindset

In 2018, CAST partnered with a New England state to launch a multi-year, state-wide professional learning opportunity designed to support educators to apply UDL to their practice. Now in its fourth year, CAST is collaborating with more than 70 schools and 600 educators from across the state. Over the four years, evidence of the UDL framework supporting educators to shift their understanding of barriers from within individual learners to within the design of the environment has emerged. The following reflections from participating educators are representative of this shift:

- “I am looking for barriers, not learning deficits.”
- “Changing our own mindsets to engage our students and identify barriers in the classroom rather than always focusing on the students was eye opening.”
- “Understanding UDL allows me to consider all my students, what they need to be successful, and what barriers are in the classroom and lessons that prevent learning from occurring.”
- “I’m making more conscientious decisions and efforts to implement strategies and options to eliminate barriers so all can access learning and share what they know.”

UDL rising to equity: more fully developing the UDL framework

Although UDL has prompted various stakeholders to begin wrestling with their orientations toward learner variability, their framing of barriers to learning, and their beliefs about the capabilities of all learners, it is important to note that exposure to UDL alone does not prompt these kinds of reflections. As with so many professional learning journeys, leveraging UDL as a tool for reflecting on one's orientations toward teaching and learning takes sustained leadership and commitment over time (Fullan, 2007; Garet et al., 2001; Knapp, 2003). Practitioners who have made these shifts in their orientations have been a part of learning communities that prioritize time to grapple with the tensions and new ways of thinking that UDL can surface.

Further, the *UDL Guidelines* are intended to be a living, dynamic tool that can be developed over time based on new research and feedback from stakeholders (CAST, 2021b). CAST intentionally called the first version of the guidelines "Version 1.0" to emphasize the beginning of an iterative process. Thus, the *UDL Guidelines*—and the UDL framework more broadly—continue to evolve to better support stakeholders to wrestle with the attitudes and beliefs that they bring to the design of learning opportunities and to push even further in terms of how UDL can be more fully developed as a lever for equity. Over the past several years, there has been a growing call from stakeholders to explore how UDL intersects with concepts such as power, privilege, oppression, and identity. For example, researchers and practitioners are advocating for UDL to make connections to Culturally Sustaining Pedagogy (CSP) (Waitoller and King Thorius, 2016), antiracism (Fitzgerald, 2020), and Disability Studies and Critical Race Theory (DisCrit) (Fornauf and Mascio, 2021). This push from stakeholders is propelling the continued iteration of UDL as a framework to support the design of more equitable learning environments.

CAST's *UDL Rising to Equity* is one example of an initiative that aims to respond to this growing call from the UDL field. *UDL Rising to Equity* is a transparent, inclusive, community-driven process to re-envision CAST's *UDL Guidelines* through an equity lens. Specifically, the process focuses on updating the guidelines to "address systemic barriers that result in inequitable learning opportunities and outcomes" (CAST, 2020). CAST is facilitating a collaborative, iterative process that includes a diversity of stakeholder experiences—including perspectives that may not have been considered in previous versions of the guidelines. *UDL Rising to Equity* focuses on fully developing the *UDL Guidelines* as a lever for designing learning environments where learners are honored, welcome, and valued—and as a lever for encouraging stakeholders to examine their own orientations and commitments toward equity.

UDL as an instructional design framework

In the past three decades, educators have discussed, debated, and developed ways to apply the guidelines to practice. The *UDL Guidelines* provide a basis and framework for inclusive instructional design. The 3 principles, 9 guidelines and 31 checkpoints that make up the UDL framework were derived from research (CAST, 2018a) and, when they were originally published, CAST provided detailed definitions of the guidelines and checkpoints as well as examples of how to apply the guidelines (Gravel and Rose, 2009; Rose and Gravel, 2010). However, in keeping with a foundational value of flexible use, CAST did not prescribe a particular way to implement the *UDL Guidelines*. Users of the *UDL Guidelines* were free to apply the principles in ways that were relevant to their students, settings, and needs. The inherent flexibility of the UDL framework is one of its greatest strengths, but also poses some challenges for UDL implementation efforts.

As a flexible framework that can be applied in many permutations and combinations to create inclusive educational environments, UDL is used in various ways and for varied purposes. In the past three decades, educators have applied UDL to curricula, courses, digital tools, and instructional environments. School districts have adopted UDL system-wide and states have recommended the integration of UDL. Researchers have applied UDL to a variety of practices and settings, using varied combinations of the guidelines and checkpoints (Rao et al., 2014). The literature on UDL includes applications of UDL in K12 and higher educational environments. Researchers have examined implementation of UDL in relation to designing inclusive environments (e.g., Kumar and Wideman, 2014; Lock et al., 2017; Scott and Temple, 2017), supporting student success in content areas (e.g., Gravel, 2018; King-Sears and Johnson, 2020; McMahon et al., 2016; Root et al., 2020), applications within digital environments (e.g., Daley et al., 2020; Dalton et al., 2011; Hall et al., 2015; Kennedy et al., 2014; Marino et al., 2014; Rappolt-Schlichtmann et al., 2013), and teacher education (e.g., Cunningham et al., 2017; Evmenova, 2018; Lanterman and Applequist, 2018; Wu, 2012). Researchers have also examined academic outcomes and socio-emotional outcomes (e.g., engagement, behavioral) in relation to the application of UDL (Ok et al., 2017).

The UDL Design Cycle: inclusive instructional design

In *Universal Design for Learning: Theory & Practice*, Meyer et al. (2014) present the core concepts that underlie the framework. First, they highlight the notion of learner variability, that every individual has different needs, abilities, backgrounds, and preferences. As described earlier in this chapter, they emphasize that learner variability is the norm in classrooms. Instead of designing for a mythical average learner, a focus of UDL is to design for all by integrating flexible options. UDL-based design also places a focus on reducing barriers in the learning environment and addressing learner variability through proactive and intentional development of flexible, supportive, and engaging learning environments (Nelson, 2021).

Educators can use UDL as part of an inclusive instructional design process. By considering UDL guidelines during the design process, it is possible to broaden the diversity of learners for whom instruction will work from the outset. UDL-based design starts with a consideration of instructional goals and learner variability. By first considering the knowledge needed to master instructional goals, educators can identify where potential barriers lie. Extending from that analysis, they can integrate flexible options and supports to address learner variability, including the varied needs, preferences, backgrounds and abilities of learners.

CAST originally defined how UDL can be applied to instructional goals, assessments, methods, and materials (Meyer et al., 2014). For educators interested in undertaking an inclusive instructional design process, Rao and Meo (2016) provided additional guidance and a systematic approach for designing with UDL during the lesson planning process. This approach, called the *UDL Design Cycle*, lays out a step-by-step approach for applying UDL to instructional goals, assessments, methods, and materials (see Fig. 1).

Similar to other instructional design processes, the *UDL Design Cycle* uses a backward design process starting with a learner analysis and linking instructional design decisions to the needs of learners. The *UDL Design Cycle* adds a uniquely inclusive focus to other models by emphasizing learner variability from the start. Teachers and instructional designers begin with a consideration of variability and analyze instructional goals in relation to potential barriers in the curriculum and learning environment. As they design instruction, decisions are made in each step to intentionally and proactively reduce and eliminate barriers and to provide supports and scaffolds that address learner variability. Table 1 depicts key considerations and questions to ask during the UDL based instructional design process.

The *UDL Design Cycle* provides a systematic way to consider socioemotional aspects of learning, in addition to cognitive aspects of learning. For example, when developing assessments (Step 3 of the cycle), educators can consider how to provide scaffolds that reduce threats for students by giving students opportunities to practice the format of assessments, providing low stake assessments (e.g., shorter weekly assessments instead of one high stakes test), and providing mastery-oriented feedback. When developing instructional methods (Step 4 of the cycle), the UDL framework provides guidance on reducing barriers in the socio-emotional realm as well by integrating supports that can help students persist and engage with learning. This includes strategies to increase relevance and authenticity, support meaningful interactions and collaborations, and promote self-regulation. Ultimately, UDL-based design focuses on creating inclusive learning environments that take into consideration the contexts for learning along with the content.

The last two steps of the *UDL Design Cycle* (Steps 5 and 6) address implementation of the lesson and reflection on whether the UDL-based elements addressed learner variability as intended. Designing with UDL can be an iterative process, building on the elements that worked well and adding flexible options and supports over time. For this reason, it is helpful to reflect on UDL-based lessons, retain the elements that supported learners, and include new strategies as needed to further reduce barriers.

Fig. 1 UDL Design Cycle. Adapted from Rao and Meo (2016).

Table 1 Considerations and questions for the instructional design phase.

<i>UDL Design Cycle</i>	<i>Considerations and questions</i>
1. Consider learner variability	What is learner variability like in my class? Consider the following attributes of your learners: • Abilities/strengths • Backgrounds/experiences • Preferences/interest • Support needs
2. Identify clear goals	State 1–2 goals in clear and simple form. What knowledge and skills are required to meet these goals?
3. Develop assessments	What are potential barriers to reaching these goals? How can I use formative assessments that provide information on student mastery toward goals? How can I develop summative assessments that have construct relevance (measure knowledge rather than the format)?
4. Develop methods and materials	Taking UDL guidelines into consideration, plan strategies that address learner variability: • What strategies can I integrate to reduce barriers? • What scaffolds can I integrate for learners to use as needed? • How can I provide flexible options and choices in relation to lesson goals? • What materials/resources can I use to enhance flexibility, choice, and support options?

Flipped, blended and online: UDL for all formats

UDL-based design can be used to support inclusive practices in all instructional formats. Whether educators are designing for traditional classroom instruction or for online formats (e.g., blended, hybrid, or fully online), they can use the *UDL Design Cycle* to reduce barriers by integrating supports and scaffolds. When designing for online and blended learning, UDL can be especially useful as a way to make decisions about the most effective ways to use varied tools and formats (Rao, 2021). In online formats, UDL-based design can provide a systematic way to consider how to blend methods, for example, when and how to use asynchronous and synchronous opportunities to ensure that students have necessary supports for learning. For example, if a teacher is teaching online and uses both asynchronous and synchronous formats (e.g., online meetings using a system like Zoom or Google Meet), they can make instructional decisions on how to reduce barriers during asynchronous instruction (e.g., providing directions using screen-casts, using multimodal formats to deliver content) and how to use synchronous meetings to ensure that learners are engaged and motivated to learn.

The COVID-19 pandemic in 2020 resulted in a rapid shift to online learning worldwide. This highlighted the need for educators to understand how to proactively design learning experiences to support students in online learning environments. Educators worldwide had to quickly develop the skills to teach online, navigating learning management systems (e.g., Google Classroom, Blackboard), web-conferencing software (e.g., Google Meet, Zoom), and various digital tools available for teaching and learning (e.g., Padlet, Flipgrid, PearDeck, Quizlet, EdPuzzle). Using the *UDL Design Cycle*, teachers can make instructional decisions about how to use these types of digital tools meaningfully to support student learning in online environments.

Online learning brings with it new barriers that may not be as prominent in face-to-face learning environments. For example, in the online learning environment, students may work more independently without a teacher present as they learn. This results in fewer opportunities to clarify questions immediately. Teachers are not able to immediately observe and assist students just in time. To reduce these types of barriers, teachers can use UDL to make decisions about how and when to integrate digital tools and instructional strategies to provide supports that benefit students in online and hybrid learning environments. For example, using the features of digital text and e-books, teachers can support independent reading activities. Features such as text-to-speech, dual highlighting, and comprehension supports built into digital text environments are powerful ways to provide multiple means of representation. To give students multiple ways to express what they know, teachers can incorporate various multimodal tools that allow students to have a choice of how to demonstrate their knowledge (using video, audio, graphics, and text). These are just a few examples of the ways that digital tools can support diverse learners in the online learning environment (Kennedy and Boyle, 2021; Long et al., 2021; Rao et al., 2021; Speight and Kucharczyk, 2021).

Several studies have explored the application of UDL to online learning in higher education environments (i.e., Coy et al., 2014; Evmenova, 2018; Hollingshead, 2018; Lock et al., 2017; Tobin, 2014). In the post-secondary environment, UDL has been applied at a course level to provide students with options to persist and engage in the online-hybrid learning format. UDL has been used to support first-generation college students, students with disabilities, and students who are culturally and linguistically diverse. Using the *UDL Design Cycle*, instructors can design courses by breaking up a semester-long course into several modules. For each module, the instructor can identify key objectives and make decisions about the instructional strategies, digital tools, and assessment formats to use to provide options for students (Rao, 2021).

UDL Reporting Criteria

Because UDL can be applied for various purposes in ways that are flexible and localized to each setting, it is necessary for educators and researchers to clearly describe their applications of UDL in order to present models and allow others to replicate best practice with UDL. To provide a structure for describing UDL implementation, the Research Committee of the Universal Design for Learning Implementation and Research Network (UDL-IRN) developed and published the *UDL Reporting Criteria* (UDL RC) in 2019. Using the UDL RC, educators can describe the UDL-based aspects of lessons, programs, and/or environments. The UDL RC provide a checklist, organized into three essential areas of UDL based design:

1. Learner Variability and Environment
2. Proactive and Intentional Design
3. Implementation and Outcomes

The UDL RC were designed for use by many stakeholders, including practitioners, researchers, instructional designers, and curriculum developers, to describe their UDL-based lessons/curricula, environments and interventions. Researchers can use the RC as they design interventions, ensuring that core components are clearly articulated and able to be replicated and used by others. Teacher educators and academic coaches can also use the UDL RC as a tool for professional development on UDL. Educators can use the UDL RC to document their UDL-based planning processes and lesson implementation for review and discussion with peers and teacher educators. The UDL RC provide a structured way to describe how UDL was applied during the instructional design process and during implementation of a lesson or intervention, and what the related outcomes were, making it easier for others to understand how UDL was applied and to replicate or adapt models for their own settings.

Conclusion

Over the course of 20 years, UDL has grown from its origins within a small group of people interested in changing conceptions of ability/disability to a widely-accepted framework for inclusive education that is used throughout the world. At its core, UDL exhorts educators to consider their values around equity and inclusion and to infuse those values into the way they design educational environments. Most importantly, UDL encourages educators to think deeply about learning, diversity, and the goals of education. Not surprisingly, that means that the UDL guidelines themselves depend upon continual reflection and revision in order to adequately reflect the learning that emerges from their application. The wide application of UDL has revealed both strengths and weaknesses of the existing guidelines.

As mentioned in this chapter, CAST has spearheaded efforts to review, revise, and update the guidelines in the light of what we have learned so far. For example, CAST's *UDL Rising to Equity* has been one way to ensure that future versions of the UDL guidelines are guided by a much more representative group than previous iterations. The process integrates a transparent, community-driven structure to re-envision the next version of the guidelines through an equity lens and to emphasize the guidelines as a living, dynamic tool, that depends on iterative feedback from a diversity of stakeholders. It is this kind of inclusive collaboration that will sustain the growth of UDL as a lever for designing equitable learning environments where learners can thrive. We conclude by sharing our predictions and visions for the future of UDL.

First, although the UDL guidelines were timely and innovative at their origin, ongoing efforts will ensure that the guidelines remain a tool that is reflective of current research. These continual updates include three major areas: (a) advances in the affective and cognitive neurosciences with special focus on the bases for individual variability in ability and disability; (b) advances in evidence-based pedagogies that have proven effective for students who have been marginalized or excluded altogether (including research on UDL practices); and (c) advances in learning technologies, especially those adaptive learning technologies that can not only teach but also learn (e.g., can learn about individual students and their optimal pathways for success).

Second, UDL was originally developed within the limited context of the USA. Although many innovative individuals have applied UDL throughout the world, the guidelines provide for them a foundation that is too narrow and rigid, particularly in their research basis and ultimately their recommendations. The rich experience derived from applying UDL internationally provides a broader and stronger foundation for UDL, making it more suitable for international application but also more flexible and inclusive to meet the growing diversity that characterizes the USA. There is much to be learned from international partners who apply UDL in various contexts; their experiences support the continued evolution of the guidelines, adding a global perspective on its application to promote inclusion and equity.

Third, although the UDL guidelines address a wide range of potential barriers to learning, they do not address all of the barriers and they do not address the barriers that are most problematic for some learners. Pointedly, for the most part, the UDL guidelines address barriers based on ability but not identity. For some students, the barriers they face have little to do with their actual abilities and much more to do with other people's perceptions (biases) about their abilities (and motivation, etc.) based on their skin color, their sexual orientation or gender, their age, their ethnic origin, etc. These implicit biases, and the barriers they (often inadvertently) erect, are much harder to address than explicit barriers. Addressing them will require thoughtful collaborations with other individuals and organizations for whom barriers of identity have already been a primary focus. Because the two kinds of barriers inevitably intersect, such collaborations will ensure that the UDL guidelines are more carefully articulated to be effective for everyone.

Fourth, the UDL guidelines were focused primarily on the barriers that arise within an individual classroom or school curriculum. But many barriers are systemic, institutional, even broadly cultural. Classrooms and curricula are inevitably embedded within such larger entities which impose various implicit and explicit biases and barriers. Since most institutions are, like classrooms, learning organizations, the UDL guidelines should apply to the barriers they impose.

Continued iteration and development are critical to the future success of UDL. We look forward to this third decade as a time of ongoing learning from stakeholders—from both within the current UDL community as well as from stakeholders whose perspectives and experiences have not yet been considered.

Since it came into discussion in the early 1970s, the idea of well-being has been strongly promoted as an individual and societal value as well as a basic psychological need (Biswas-Diener et al., 2005; Diener and Lucas, 2000; OECD, 2017; Ryan and Deci, 2001; Strack et al., 1991). Well-being as an indicator of quality of life is important for human health, development, and flourishing. The basic objectives of well-being research are to identify the core elements, predictors, and outcomes of well-being and to test programs that aim at improving well-being. Well-being emerged as a research topic of multi- and transdisciplinary interest as it is expected to influence various dimensions of individual and societal life. Specifically, positive psychology has dedicated itself to research in well-being (Linley et al., 2006). As regards well-being and learning, major contributions are acknowledged from disciplines that focus on schools, learning and instruction such as educational sciences and educational psychology. Understanding learners' needs for both academic achievement and well-being is crucial for 21st century education (Seligman et al., 2009).

Understanding well-being

The variety of disciplines that investigate well-being has led to different research approaches and definitions of well-being (e.g., Diener, 1984; Hascher and Waber, 2021; Larsen and Diener, 1987; Veenhoven, 1991). Across this variety, four general lines of the conceptualization of well-being can be identified: (1) Well-being is defined as a specific emotional quality of feeling well. (2) Well-being is used as a supra-term for various positive emotions such as enjoyment, pride, satisfaction etc. (3) Well-being is used as a supra-term for the absence of diverse negative emotions, psychological and physiological variables such as anxiety, depression, exhaustion, or burnout. (4) Well-being is defined as a multi-dimensional concept combining specific positive and negative dimensions (e.g., satisfaction and positive emotions combined with an absence of emotional exhaustion).

Well-being in psychology and education

As a psychological term, well-being usually refers to a subject's own feelings and cognitive evaluations and is defined as a multi-dimensional construct (Ryff and Keyes, 1995). A set of dimensions covering emotions and evaluations are considered to form well-being as can be seen in the PERMA-model of Seligman (2002), which consists of positive emotion, engagement, relationships, meaning, and accomplishment. For example, if individuals experience happiness or pride and evaluate their actual situation positively, they are expected to feel well; on the contrary, if individuals experience sadness or anger and evaluate the situation negatively, they experience a low level of well-being. Feelings and evaluations depend on a person's previous experiences, expectations, goals, and values. Thus, reasons for positive or negative emotions and evaluations may differ across individuals. Well-being also consists of both mental and physical components; that is, a person's thoughts as well as body sensations have to be considered. Defined this way, well-being differs significantly from a single feeling of satisfaction or from a singular emotional experience like enjoyment.

Along with the multi-dimensional character of well-being, different forms of well-being are discussed. According to the World Health Organization's definition of health, well-being can be specified as a psychological, physical, or social form (e.g., WHO, 2000). Ryan and Deci (2001), for example, suggested a distinction between hedonic well-being that is predominantly related to

positive affective experience and need fulfilment and eudemonic well-being that is based on the experience and pursuit of a meaningful life. Also, forms of domain-specific well-being can be differentiated, such as workplace well-being that is defined as consisting of organizational well-being and subjective well-being (Burns and Machin, 2013).

Due to the co-existence of positive and negative events in life, well-being can be described by the interaction of positive and negative aspects: The more positive life is in general or the more positive specific relevant life domains are experienced, the better the well-being; negative feelings and negative evaluations of important circumstances or events in one's life result in lower levels of well-being. Thus, to understand and explain a person's well-being, positive and negative dimensions must be taken into account simultaneously, and well-being can be understood as a "positive imbalance" that represents a dominance of positive emotions and evaluations over negative emotions and evaluations (Hascher et al., 2021). The more pronounced this difference between the positive and negative dimensions, the higher the well-being.

Well-being can develop in a short- or long-term perspective (e.g., Kim-Prieto et al., 2005). In the short-term, actual well-being is situationally determined and an expression of a predominance of current positive emotions and cognitions while experiencing a situation. This might include, for example, students feeling well while working in pairs on a problem-solving task during mathematics class or teachers feeling well while collaborating with a colleague in preparing a set of lessons. In the long-term, habitual well-being is sustainable and an indicator of a more general, subjective evaluation of life situations and circumstances—for example, feeling well in school overall apart from single situations that are negatively experienced. This means, repeated positive experiences such as feeling enjoyment, mastering academic challenges, or feeling competent in school combined with a low number of negative occurrences such as feeling stressed, losing control, or feeling under pressure will lead to well-being in school. Short-term and long-term well-being are related to each other as habitual well-being develops through frequent experiences of short-term well-being, and short-term well-being is determined by the frame of habitual well-being. However, habitual well-being cannot be seen as a simple or accurate aggregation of actual well-being. This is because specific experiences of actual well-being can contribute differently to habitual well-being, in that actual well-being in situations of special importance may have a stronger impact on well-being than situations of lower relevance.

For the assessment of well-being, an array of quantitative and qualitative instruments exists, ranging from affect-balance-scales to well-being questionnaires to event sampling methods and happiness interviews (Andrews and Robinson, 1991; Diener, 1984; Diener and Biswas-Diener, 2000; Hascher and Waber, 2021; Lucas et al., 1996). Of specific importance for the accurate assessment of well-being is a multi-faceted approach. Various dimensions of student well-being, for example, the emotional and cognitive as well as the positive and negative, need to be considered. Single items are less valid for measuring the complexity of well-being, and multi-method assessments which explicitly integrate different perspectives on well-being are recommended.

Predictors and outcomes of well-being

Well-being is sensitive to many factors. The more general well-being is defined and measured the more sources can influence it (Diener, 1984). Although researchers have attempted to specify predictors for the different components of well-being, research so far has only limited been successful in uncovering the most potent variables. However, social relationships turn out to play a crucial role for the development of well-being. For example, social support can enhance an individual's functioning and serve as a buffer against adverse experiences (e.g., Chu et al., 2010). Based on Bronfenbrenner's paradigm (1979) that the individual is embedded within and interacts with different ecological systems and the notion that this interplay determines well-being, three main categories of predictors have been identified:

- (1) Well-being is influenced by living conditions such as an individual's financial or health status that are of relevance for a general evaluation of life and contribute directly to well-being. Other contextual factors such as an organizational or school culture might be intertwined with specific resources (e.g., positive social interactions), which influence the fulfilment of goals and aspirations and, as a result, well-being (e.g., Diener et al., 1995).
- (2) Personal characteristics can predict well-being. In addition to gender, the role of introversion versus extraversion for well-being has been identified (e.g., Vittersø and Nilsen, 2002). Extraverted individuals seem to experience more positive situations in life and, thus, feel better than more introverted persons (bottom-up approach). Also, extraverted individuals might interpret life more positively, react in a more positive way to life events and circumstances, and feel better than more introverted individuals (top-down approach).
- (3) Subjective and temporal differences have been shown to affect how an event is evaluated and interpreted. A person's evaluation might be based on various points of reference (e.g., Stein et al., 1997), such as social comparisons, individual goals and expectancies, processes of adaptation to new life-circumstances, coping with challenging situations, control beliefs or causal attributions.

As with the array of predictors, the outcomes of well-being are recognized to be manifold, with strong support for the idea that well-being can contribute to successful adjustment, positive development, and a meaningful life, whereas a lack of well-being may be harmful for the individual (e.g., Wood and Josephs, 2010). Regarding the relevance of well-being for learning, the idea that well-being supports learning and development across the lifespan has been broadly accepted (Hascher, 2010). According to the Broaden-and-Built Theory (Fredrickson, 2001), well-being is expected to enable positive experiences that, like positive emotions, support cognitive functioning and learning. Although there might be varying effects due to contextual factors, studies have confirmed that well-being affects various aspects of learning and achievement (e.g., Abele et al., 2005). Positive mood might support

more creative, holistic, flexible thinking, and might be associated with better performance. Empirical findings also suggest that positive learning emotions are aligned with factors that influence learning and achievement, such as academic-ability concept, academic interest and engagement, time-management strategies, and meta-cognition (e.g., Efklides and Petkaki, 2005; Reschly et al., 2008). These positive associations are also mirrored in the concept of *flourishing* that more generally represents high levels of well-being (Seligman, 2011). Regarding educational settings such as schools, research reveals that not only negative but also positive emotions deserve closer attention because of their beneficial effects on learning and achievement as well as reciprocal effects between emotions and students' and teachers' learning and achievement (Frenzel, 2014; Pekrun and Linnenbrink-Garcia, 2012).

Well-being and learning in school

During recent years, student and teacher well-being have gained increasing attention. There are several reasons for this. First and foremost, well-being has been recognized as an important aspect of successful education and individual growth, as learning is based on an interplay of cognitive, motivational, and emotional factors. Second, schools have increasingly developed as caring communities for students and teachers that aim to support individual growth as well as social skill development by incorporating well-being as a goal of school improvement. Third, well-being has been acknowledged as a protective source in facing and coping with societal challenges that possibly increase psychological and emotional problems (Green et al., 2012). With regard to the multi-dimensional nature of well-being, well-being in school can be described by several components that equally can be applied to student and teacher well-being (see Fig. 1).

For students and teachers alike, well-being in school may be viewed as a subjective, emotional, and cognitive evaluation of school reality (Van Petegem et al., 2006). Well-being in school is seen as an imbalance resulting from positive emotions and cognitions related to the school context that outperform negatively experienced and evaluated aspects of the school context.

Understanding student well-being

Student well-being has been recognized as a pedagogical aim in educational theory and practice. However, there has been some controversy around the issue. Sceptics have voiced doubt about the solely positive function of well-being and asked if student well-being could be harmful (Boekaerts, 1993). They stress the likelihood of neglecting the attainment of academic goals for the benefit of a positive atmosphere in school. This scepticism is unjustified, as there are several strong reasons for maintaining and fostering well-being in school (Hascher and Hagenauer, 2020). Apart from the idea that well-being in school serves as a value in itself, it has been found that student well-being is an indicator of successful psychosocial adjustment to school (Buyse et al., 2009). Also, there is empirical evidence that student well-being positively affects students' learning processes and learning outcomes (see Hagenauer and Hascher, 2014; Hascher, 2011; Morinaj and Hascher, 2019). Although student well-being might not directly enhance an individual's achievement, it is intertwined with various factors that contribute to effective learning and is an important criterion for a positive school climate which is necessary for students' learning—particularly in a highly structured, achievement-oriented, non-optional learning context such as a school (UNICEF Office of Research, 2017). Student well-being can also serve as a resource for coping with failure as well as social and academic problems. Students who feel well in school may also transfer their positive attitudes toward learning and achievement in school to learning and achievement in general. Furthermore, student well-being is a crucial indicator of children's and adolescents' health status (Inchley et al., 2016) and mirrors school quality and effectiveness (Bradley et al., 2018).

Among studies of student well-being, various views as to how to investigate student well-being can be found. One important difference is how precise and detailed student well-being is defined and how strongly it is related to the school setting. An overview of the research reveals five different approaches to student well-being (see also Hascher, 2008):

Fig. 1 Six dimensions of well-being in school.

- (1) Students are asked about aspects of their general mood states, mostly negative states like depression (e.g., Benjet and Hernández-Guzmán, 2002; Undheim and Sund, 2005). Although student well-being is not directly addressed and school context might be neglected, the results can help to elucidate how students generally feel.
- (2) Students are asked to report their well-being by using a general well-being scale for children or adolescents (e.g., Jin and Moon, 2006; Huang and Chien, 2013; Konu et al., 2002). Both dimensions of well-being, positive (e.g., enjoyment) and negative (e.g., worries), might be addressed, and the results can contribute to an understanding of well-being in young individuals.
- (3) Well-being is operationalized by a selective combination of various emotional, social, and cognitive school-related variables. These include, for example, test anxiety, social integration into the classroom, and satisfaction in school (Huebner et al., 2001). Results from these studies provide insight into school-specific psychological phenomena that are related to student well-being.
- (4) Student well-being is defined and investigated as a specific quality in the school setting. This research explicitly addresses student well-being, school well-being, or well-being in school (e.g., Engels et al., 2002; Hascher, 2003; Hascher and Hagenauer, 2020; Morinaj and Hascher, 2021) and is grounded in a theory of psychological well-being. With its explicit focus on the school environment, this research can be seen as a domain specific approach to student well-being. The strengths of these studies lie in their contribution to a deeper understanding of student well-being, its correlates and predictors.
- (5) In terms of the WHO definition of health, student well-being is discussed under the broader perspective of health and health promotion (e.g., Konu and Linthonen, 2005, 2006). Related to school as an important context for children and adolescents, these studies contribute to an understanding of student well-being as a crucial component of general physical and mental health.

What does empirical evidence tell about student well-being?

In asking the question about well-being in school, an interesting contradiction can be found: Repeatedly, it has been shown that school can turn into an aversive context and central source of stress for children and adolescents (e.g., OECD, 2017; Undheim and Sund, 2005). Accordingly, when asked about daily experiences in school, students report a dominance of negative situations and emotions (Hascher, 2007, 2008). However, when asked more generally about well-being in school, students in many countries indicate average, or even high, scores (OECD, 2017). One possible explanation for this discrepancy is that the results depend on the way students are asked about their school. To report about everyday events in school may lead to a focus on negative aspects because students feel a stronger need to communicate them. Conversely, a questionnaire on student well-being that stresses negative as well as positive components is better able to take both sides of school into consideration simultaneously. Another explanation is given by the theoretical assumption that student well-being is more than simply a compilation of daily events. A more holistic view on school leads to different, more positive, results than a focus on singular experiences.

Independent of the method of measurement, low to moderate inter-individual differences in student well-being have been empirically confirmed (see Hascher and Hagenauer, 2020; Konu and Linthonen, 2006; Morinaj and Hascher, 2021). High achieving students feel better in school than low achievers. Girls report higher scores on well-being but are also more likely to describe higher scores on negative components like physical complaints, in comparison to boys. Younger students feel better in school than students in higher grades; however, toward the end of compulsory education, an increase of student well-being can be found. It has to be noted, that these differences in student well-being cannot be attributed exclusively to individual characteristics, as learning conditions in terms of the school setting, instructional quality, and teaching subjects are likewise relevant (see Opdenakker and Van Damme, 2000; Van Petegem et al., 2006). Schools have been shown to differ in their level of student well-being, indicating the relevance of school culture variables. Also, students report better well-being scores in schools with a higher academic ranking in comparison to schools with a lower academic ranking. Higher levels of student well-being are reported in lessons with a predominant student orientation in comparison to teacher-centred lessons. Student well-being differs across subjects showing that highly selective subjects are more often associated with lower well-being than subjects with lower achievement pressure. With regard to the sub-dimensions of student well-being, interesting differences can be found (e.g., see Hascher and Hagenauer, 2020; Van Petegem et al., 2007). Students report low degrees of physical complaints and equally low degrees of social problems. However, worries in school are frequent, and students often report a lack of enjoyment in school. Students' intrinsic motivation correlates positively with student well-being, whereas test anxiety correlates negatively with student well-being.

Predictors of student well-being

According to research on general well-being, there might be an array of sources that contribute to student well-being (see Fig. 2). More systematically, predictors of student well-being can be divided into three main groups:

- (1) Student well-being is influenced by *contextual* conditions, primarily by the school and learning environment. Characteristics of school structures as well as school-specific variation in terms of action plans in school, school culture, pedagogical orientation, infrastructure, and facilities are expected to have a distinct impact on student well-being. Situation-specific classroom factors such as the quality of instruction, facilities, participation in the classroom or the fulfillment of basic needs are of comparable importance. Teachers, as well as classmates, play an essential role in student well-being (Hascher, 2003; Van Petegem et al., 2007). Teachers' pedagogical and social competencies and a supportive teaching style, along with high quality teacher-student relationship, have been shown to be predictive of student well-being (Hagenauer et al., 2015), whereas pressure to achieve, lack of instructional quality along with social isolation and a problematic teacher-student-relationship can be harmful for student well-being (Baumeister and Leary, 1995; Hall-Lande et al., 2007; OECD, 2017). Similarly, the social support of peers, a cohesive

Fig. 2 Predictors of student well-being.

classroom, and positive interactions during breaks foster student well-being by promoting positive attitudes toward school and student academic self-concept and by preventing social problems in the classroom. Social discrimination in the classroom or rejection by peers, however, reduces student well-being by increasing social problems in school. Additionally, students' living conditions, family structure, parental academic orientation, and school orientation of peers can influence student well-being (Martin, 2005).

- (2) Student well-being can be predicted to some degree by personal characteristics. In regards to gender, it has been repeatedly found that girls express higher scores of positive as well as negative dimensions of student well-being. This may be because they experience student well-being more intensively or because they are more open to reporting their student well-being (Brebner, 2003). There is also evidence that predictors of student well-being show gender-specific relevance (Bergman and Scott, 2001; Liu et al., 2016; Løhre et al., 2014). In addition to gender, school-related factors such as engagement and effort, self-efficacy and control beliefs, goal orientation or tolerance to frustration might influence student well-being, as they can contribute to students' ability to manage academic challenges. Factors that support success in school also help to foster student well-being.
- (3) Although some context and personality variables might directly influence student well-being, most effects may result from person-environment interaction. The interaction is represented by subjective differences in how school-related conditions and events are evaluated and interpreted. For instance, differences in student evaluations can result from social comparisons, processes of adaptation to the school situation, personal interests, coping with challenging situations, causal attributions, etc. These variables affect how school is perceived and how an individual's situation is related to the context, and they are powerful for students' self-evaluations. These variables can have a direct impact on student well-being as well as serve as mediators between school conditions, personal characteristics, and student well-being. Accordingly, the alignment of individual goals, values, and expectancies with the school situation seems to be crucial for the development of student well-being—the better the alignment, the higher student well-being.

Understanding teacher well-being

Teacher well-being in school as an indicator of the quality of school life has also been considered as a crucial factor for teachers' functioning and mental health. Teacher well-being is acknowledged as a major driver of effective teaching (Duckworth et al., 2009) and a preventive resource against emotional exhaustion, burnout and job dismissals (McCallum et al., 2017; Renshaw et al., 2015; Skaalvik and Skaalvik, 2018). Among the plethora of empirical studies on teacher well-being (for an overview, see Hascher and Waber, 2021), various aspects of psychological functioning such as job satisfaction, intrinsic motivation, flow, and emotions at work or dysfunctional factors such as exhaustion, burnout or stress at work are studied as indicators of teacher well-being.

Among the various approaches, job satisfaction has often been considered a main indicator or core element of teacher well-being, although it is frequently defined as a cognitive job attitude, neglecting the emotional dimension of well-being (e.g., Veldman et al., 2013). It has been found that teachers experiencing high satisfaction differ from less satisfied teachers in terms of subjective health and thoughts about leaving the job. Low satisfaction seems to go along with stress and unsuccessful coping strategies. However, the level of job satisfaction has been found to vary between different occupational areas: For example, teachers might be highly satisfied with their core professional tasks (e.g., work with children, instruction, and teaching) but dissatisfied with organizational factors (e.g., classroom size, number of administrative tasks) and professional support. Also, significant differences in terms of school type have been reported, indicating high levels of job satisfaction for nursery and primary school teachers in comparison to secondary teachers. It must also be noted that relevant predictors of job satisfaction (e.g., interaction with students) can simultaneously serve as causes of stress. As a result, a more differentiated approach to satisfaction and teacher well-being in terms of the quality of experience and the evaluated subject is recommended. For example, different forms of satisfaction can be identified (e.g., Inauen et al., 2015).

Interestingly, although it has been repeatedly mentioned that teacher well-being is a risk, research has shown that the majority of teachers are satisfied with their job and feel well in school (Hascher and Waber, 2021). At the same time, however, increasing

evidence has revealed that teachers experience high levels of stress. These results point to the necessity to carefully define teacher well-being and factors that might influence it. There is a need for a more precise conceptualization of teacher well-being. Based on the original idea of well-being as a multi-dimensional construct, teacher well-being could be defined as a positive imbalance of work-related dimensions. Teacher well-being could be seen as a clearly defined set of positive dimensions that are more pronounced than a clear set of negative dimensions. This definition could also help differentiate teacher well-being from a sole absence of health issues, stress, burden, or burnout symptoms.

Predictors and outcomes of teacher well-being

According to research on general well-being, various predictors for teacher well-being can be assumed. Generally, they can be divided into individual and contextual factors and their interplay. Regarding contextual factors, the workplace is the main source of teacher well-being. Diverse conditions of working in schools and teachers' subjective perceptions need to be taken into account. These are, for instance, high autonomy, high responsibility for students' learning outcomes, support of colleagues, a continuous process of educational reforms, high achievement-pressure due to school evaluation and assessment, challenging task of handling disruptive student behavior. Furthermore, a differentiation of intrinsic factors, like contributions to children's education and development, and extrinsic factors, like salary and social status, are thought to be helpful in understanding the factors that facilitate or hamper teacher well-being.

Resources at work are of considerable importance for teacher well-being (Salanova et al., 2006). Two forms of resources and their interaction can be differentiated: personal resources (e.g., self-efficacy beliefs) and organizational resources (e.g., autonomy and social support at work). Research on personal resources confirms that high self-efficacy beliefs can foster job satisfaction and teacher well-being (e.g., Capone and Petrillo, 2018). Similarly, organizational resources have been shown to influence teacher well-being (e.g., Ilgan et al., 2015), although the relationship between these constructs may be bidirectional. For example, organizational resources may influence teacher well-being, which, in turn, may affect future personal and organizational development. Among the array of contextual factors, social relationships have been repeatedly confirmed as a major source of teacher well-being (Hascher and Waber, 2021). Teaching as a social profession that is based on interactions with students, colleagues, and parents seems to be specifically vulnerable to social factors with social interactions at the heart of teacher well-being and crucial in fostering teacher well-being. Positive teacher-student-relationships nourish teachers' needs for social relatedness (Collie et al., 2016; Klassen et al., 2012; Spilt et al., 2011) and they mirror a successful fulfilment of teachers' role as educators that, in turn, has been shown to promote teacher well-being.

What are the possible effects of teacher well-being with regard to learning? Although empirical evidence is scarce and only few longitudinal studies have been conducted, three main effects have been identified. First, teacher well-being influences teacher learning and supports teacher professional development directly or indirectly. Teaching is known as a very challenging profession that requires continuous professional development. As a protective source against teacher stress, teacher negative affect and burnout (Renshaw et al., 2015; Vazi et al., 2013), teacher well-being can contribute to individual motivation for in-service training and a supportive learning environment alike. With its association with teaching professional values, job satisfaction, and social support, and the experiences of meaningful work (Brunzell et al., 2018; Tang et al., 2018), teacher well-being can foster the development of individual resources and strengths that also might positively extend to the classroom and school climate. Second, teacher well-being has been found to be associated with quality teaching (Turner and Thielking, 2019). Teachers who feel well in school are more likely to engage in instruction, provide individual learning support for students, and support school improvement action plans. It has also been found that students' perceptions of interpersonal teacher behavior that predict student well-being are related to teacher well-being (Van Petegem et al., 2007). Third, teacher well-being seems to influence teachers' professional development such that a dominance of negative emotions can impede their willingness to implement educational reforms (e.g., Borko, 2002; Clement, 2014).

Supporting student and teacher well-being in school

Along with growing demands on schools, such as achievement pressure through high stakes testing or educating for 21st century skills and reports about increasing student and teacher mental health issues, the importance of student and teacher well-being has been amplified. Accordingly, there is broad agreement that schools need to cultivate a social climate that is characterized by physical and emotional safety, physical and mental health, as well as learning support and enjoyment (Hascher, 2003; Roffey, 2012; Shoshani and Slone, 2013). Also, the fulfilment of students' and teachers' psychological needs alike is seen as a valuable contribution to a school in building up a supportive learning environment. Moreover, empirical evidence suggests that student well-being and teacher well-being interact (Coleman, 2009; McCallum and Price, 2010).

Although some schools may intuitively succeed in fostering well-being in school, one can expect a high probability of failure if a school does not deliberately care about student and teacher well-being. Support for those schools might be given through intervention research findings that examines the effectiveness of specific programs on well-being in school. Intervention research related to well-being in school has been dedicated to the individual, to groups, or the whole school. Intervention programs that aim at fostering well-being in school have been based on different approaches such as mental health (e.g., Dawood, 2013; Simovska and McNamara, 2015), positive psychology (e.g., Green et al., 2012; Sin and Lyubomirsky, 2009), self-determination theory (Cheon et al., 2014), school improvement initiatives regarding school climate (Bradley et al., 2018) or socio-emotional learning (Durlak et al., 2011). Common to all these programs is the shared idea of the need for a school environment that capitalizes on

the strengths of the individual, the positive power of the group and community, and the efficacy of an educational setting that is dedicated to offering the best possible opportunities for students' and teachers' learning and development.

Across the different approaches to supporting well-being in school, most interventions have been found to hold considerable potential for establishing a caring and empowering learning climate (e.g., Denny et al., 2011). Although effect sizes have usually been shown to be low to moderate, converging evidence indicates that well-being in school can be maintained and improved. Ideally, well-being interventions have been targeted to teachers as well as students, have been integrated into the curriculum instead of providing an additional or extra-curricular program, and have been closely related to students' and teachers' roles in school (e.g., Shankland and Rosset, 2017). Following a whole-school-approach has considerable potential for sustainable school improvement (Quinlan and Hone, 2020; Shoshani and Steinmetz, 2014). These results are encouraging, as they support the notion that well-being in school can be significantly fostered. The effective implementation of strategies that equally boost student and teacher well-being and support the alignment of academic/professional learning and well-being can be regarded as of utmost importance for future research and practice.

Future perspective on well-being and learning

Around the globe, educational systems and schools, in particular, have recognized the importance of teacher and student well-being. This is based on the finding that well-being can contribute to learning and educational success as much as other factors such as motivation, cognition, or social interaction. Given the complexity and the multi-dimensional character of the construct of well-being, a broad range of conceptualizations and models exists. Equally, a variety of factors that influence well-being has been identified. This complexity might be enriching, but the existing ambiguity in definitions and interrelations of constructs can also blur our understanding of well-being. Consequently, this might hamper discussion about well-being in school and its relationship with learning. Thus, it would be helpful to identify some core dimensions of well-being and to define more precisely the specific quality of well-being such as a positive imbalance where positive emotions and cognition outperform negative emotions and cognition.

In the future, well-being and learning need further careful attention in research and practice. It is important to elucidate the interplay between well-being and learning. Reciprocal effects that show the role of well-being for learning and the importance of learning for the development of well-being need to be investigated. Specifically, research is needed that identifies how well-being in school and learning can best be fostered. An answer to this question might be based on a sound partnership of researchers and school practitioners who collaboratively develop and evaluate programs to promote well-being in school such as self-regulation trainings, resilience trainings, social competence trainings or health education. As well-being is related not only to the individual but also classrooms and school teams, a whole school approach that takes various levels into account might be helpful.

EDITORS IN CHIEF – BIOGRAPHIES

Robert J Tierney

Rob Tierney is an international educator whose passion is for developing research partnerships to address local literacy needs with educators in different countries. Rob began his career as a classroom teacher in Australia, then proceeded to work in the United States, Canada, Australia and China. He is Dean Emeritus and Professor Emeritus of Language and Literacy Education at the University of British Columbia, the former Dean and Honorary Professor of the Faculty of Education and Social Work at University of Sydney, and a Distinguished University Professor at Beijing Normal University. In the United States, he has served on the faculties of the University of Illinois, University of Arizona, The Ohio State University, Harvard University, and the University of California. Rob has written a number of books and numerous articles on literacy especially related to global issues, diversity, and literacy development. His most recent book was entitled *A History of Literacy Education: Waves of Research and Practice* published by Teachers College Press in 2021. During his tenure as an educator, he has served as the President of the International Literacy Association, President of the Literacy Research Association, an Editor for the *Reading Research Quarterly*, the President of the Association of Canadian Deans of Education/ L'Association Canadienne des Doyens et Doyennes d'éducation, as well on a number of committees and boards for professional groups and government and nongovernment

agencies. In addition, he has been involved on a range of groups on projects globally including in Africa and Asia including for UNESCO, Children's Television Workshop, and Apple Computer.

Fazal Rizvi

Fazal Rizvi is an Emeritus Professor of Global Studies in Education at the University of Melbourne, as well as at the University of Illinois at Urbana-Champaign. He is also a Visiting Professor at the Universities of Turku in Finland and Pretoria in South Africa. He has written extensively on issues of identity and culture in transnational contexts, globalization and education policy, and Australia-Asia relations. He has published widely, and his book, coauthored with Bob Lingard, *Globalizing Education Policy* (Routledge 2010) is used widely in courses around the world. A sequel to this book, *Reimagining Globalization and Education* (Routledge 2022) has been published recently. Fazal is currently researching educational reform in Bhutan. He is a Fellow of the Australian Academy of the Social Sciences, a past Editor of the journal, *Discourse: Studies in Cultural Politics of Education*, and a past President of the Australian Association of Research in Education.

**Kadriye Ercikan**

Kadriye Ercikan is Vice President of Research and Measurement Sciences at the Educational Testing Service and Professor Emerita at the University of British Columbia. She is responsible for ETS's foundational and applied research and psychometric support of ETS's major testing products and contracts, and the NAEP contract for ETS. Her research focuses on validity and fairness issues and sociocultural context of assessment. Her recent research includes validation of score meaning using response processes, use of response process data for comparing groups and examining fairness and validity of interpretation, and use of scores from artificial intelligence-based automated scoring.

Ercikan is a Fellow of the International Academy of Education. Her research has resulted in 6 books, 4 special issues of refereed journals, and over 100 publications. She was awarded the AERA Division D Significant Contributions to Educational Measurement and Research Methodology recognition for another

coedited volume, *Generalizing from Educational Research: Beyond Qualitative and Quantitative*

Polarization, and received an Early Career Award from the University of British Columbia. Ercikan has been selected to serve as the NCME Book Series Editor (2021–2026).

SECTION EDITORS

Jason Beech is Associate Professor (Global Policy) at the University of Melbourne and visiting professor at Universidad de San Andrés in Buenos Aires where he holds a UNESCO Chair in Education for Sustainability and Global Citizenship. He is senior researcher of the National Council for Scientific and Technical Research of Argentina (CONICET), and Associate Editor of *Education Policy Analysis Archives*. He has been a member of the Board of Directors of the Comparative and International Education Society (2014-2016). Jason has published extensively on the globalization of knowledge and policies related to education. He has also written and is passionate about the challenges of educating for global citizenship and a sustainable future. He has taught in several universities in the Americas, Europe and Australia.

Professor Qing Gu is Director of the UCL Centre for Educational Leadership and Professor of Leadership in Education. She is the Past Chair of the *British Association of Comparative and International Education* (BAICE), Co-Editor of *Teachers and Teaching: Theory and Practice*, Associate Editor of *International Journal of Educational Development*, a member of the Research Standing Committee of the World Council of Comparative Education Societies (WCCES), and a member of the Research Evidence and Impact Panel for the Leadership College for UK Government. Professor Gu has directed and codirected many government and research council funded projects in the areas of teacher professional development, school improvement, and systemic reform and change. She has led a £1.9 m UK Economic and Social Research Council (ESRC) funded project *Schools as Enabling Spaces to Improve Learning and Health-Related Quality of Life for Primary School Children in Rural Communities in South Africa*. Some of her books have been translated into Chinese, Japanese, and Spanish.

Professor Smith is a New Zealand Maori of Te Aitanga a Hauiti, Ngati Porou, Kati Mamoe Ngati Apa, Ngati Kahungunu descent. He is a highly regarded and internationally recognized, Maori educationalist and scholar. He has been at the forefront of transforming Maori and Indigenous social, economic and cultural conditions through re-developing education and schooling outcomes. His work links theoretical thinking and practical applications within an ongoing cycle of transforming praxis.

Professor Smith trained as a teacher at Auckland Teachers College and taught in Auckland schools. He also lectured in Education at the Auckland College of Education. He was one of the first teachers and developers of a Kura Kaupapa Maori, an alternative, Maori philosophy and principles-based School. These Maori immersion schools have grown from a single entity in 1988 to over seventy-five publicly funded schools in 2015. His theoretical leadership in the Education Department at the University of Auckland helped inform the emergence of Maori Education as a distinct field of study across the New Zealand Tertiary Sector. This work has encouraged a wide range of academic studies focused on overthrowing persisting inequities within and as a result of education and schooling in New Zealand. His significant contribution to New Zealand education is to be seen in his work related to Kaupapa Maori as a theory of Transformative Praxis. All of these elements derive from his PhD research entitled, "The Development of Kaupapa Maori: Theory and Praxis (1997)".

Professor Smith's later academic work centered on developing theoretically informed strategies related to transforming high and disproportionate levels of Maori cultural, political, social, educational, and economic marginalization. He has been a significant scholar involved in the emergence of Tribal "universities" institutions (Wananga) and is the former foundation Chair of the Council for Te Whare Wananga O Awanuiarangi. He led the successful Treaty of Waitangi Claim and settlement for Awanuiarangi. In his former position as Pro Vice Chancellor (Maori) at the University of Auckland, he was responsible for developing significant structural change within the institution while working within the Office of the then Vice Chancellor, Dr. John Hood. Notable achievements included implementing a Maori development strategy within the University which required all Deans to be responsive in their performance results for Maori and Pacific advancement; the oversight of the Proposal and winning of a National Centre of Research Excellence (Nga Pae o te Maramatanga); the initiation of the Maori and Indigenous doctoral program aimed at creating 500 Maori PhD graduates across the country in five years; the recruitment of top Maori academic scholars into the University of Auckland; the development of Kaupapa Maori as a theory of transformative praxis and which has had national and international influence. Professor Smith also served on the University of Auckland Council for three years as the Professorial representative for Academic staff.

In 2007 Professor Smith accepted a role as the Universitas 21 Distinguished Visiting Professor in Indigenous Education hosted by the University of British Columbia (within the Faculty of Education). Although the position was initially intended for two years, the role was extended for a further three years. While situated at the University of British Columbia, Professor Smith also chaired the Educational Policy Studies Department for three years. These positions allowed engagement with many Canadian universities as well as other universities across the world.

Professor Smith has made significant contributions to the political, social, economic, and cultural advancement of Maori and indigenous communities in New Zealand and around the Pacific Rim. He has worked extensively with other Native/Indigenous/First Nation's peoples across the world, including in Canada, India, US mainland (including extensive work in Hawaii and Alaska), Norway, Taiwan, Chile, Australia, as well as with selected Micronesian and Pacific nations. He is a regular contributor to national and international forums and conferences. Professor Smith has been an authoritative voice within the critical debates on *social, cultural and economic inequality* both in New Zealand and abroad, and he maintains a strong influence in the Maori/Indigenous languages revitalization movements.

Professor Smith stepped down from the administrative position of CEO/Vice Chancellor at Te Whare Wananga o Awanuiarangi in 2015 after eight years in the role. He resumed his academic research and writing career. In 2019 he was invited to take up a special Chair – Te Toi Ihorei ki Purehuroa – A "distinguished Professorial position at large" established for him at Massey University.

Professor Smith has been recognized and honored for his international contributions, receiving an Honorary doctorate (D.Litt.) from the Okanagan University College in 2005, and an Honorary doctorate (LLD) from the University of Northern British Columbia in 2013; he was elected as a Fellow of the American Education Research Association in 2014, and was awarded a Queens Honour – a CNZM in 2014. He was given the Prime Minister's Life-time Achievement Award (2017); and received the Te Ururangi National Award for Education (Matariki Awards, 2019).

Professor Smith is married to Professor Linda Tuhiwai Smith and they have one daughter and two mokopuna (grandchildren).

Therese N. Hopfenbeck is Professor of Measurement Analytics in the Melbourne Graduate School of Education, The University of Melbourne. Before starting her position in Melbourne, she was Professor in Educational Assessment and Director of the Oxford University Centre for Educational Assessment. She is a Visiting Fellow at Kellogg College, University of Oxford, elected Vice-President of *The Association for Educational Assessment-Europe* and Lead Editor of the journal *Assessment in Education, Principle, Policy and Practice*. Dr. Hopfenbeck's research agenda focuses upon bridging research on self-regulation and classroom-based assessment and making sense of international large-scale studies in education. In collaboration with Professor Nancy Perry, University of British Columbia, she is currently leading an international network of researchers disseminating classroom-based research, funded by Social Sciences and Humanities Research Council of Canada (2020–2022). She is also currently Principal Investigator for two research projects funded by IB, on critical thinking in PYP schools internationally and evaluation of education reforms in Kent, UK (2020–2022). In 2020, she led the research on Critical Thinking in the Diploma Program in Australia, England, and Norway (<https://ibo.org/research/outcomes-research/diploma-studies/critical-thinking-skills-of-dp-students/>). Dr. Hopfenbeck was Principal Investigator for the PISA (2022) study in England, Northern Ireland, and Wales, in collaboration with Pearson UK (2018–2023). She was the Research Manager of PIRLS (2016), funded by The Department of Education, UK.gov, and Principal Investigator of a major ESRC-DFID research study, Assessment for Learning in Africa (ES/N010515/1) (2016–2019).

Since coming to Oxford in 2012, she has been the recipient of funding from ESRC-DFID, OECD, The Norwegian Research Council, Education Endowment Foundation, State Examinations Commissions Ireland, Jacob Foundation, and the International Baccalaureate totaling more than £2 mill in addition to a single grant of £4 mill in collaboration with SLATE: Centre for the Science of Learning & Technology at the University of Bergen, Norway. Prior to her appointment at Oxford, she worked as a postdoctoral researcher at the University of Oslo's research group for Measurement and Evaluation of Student Achievement at the Unit for Quantitative Analysis of Education (2010–2011). She is Adjunct Professor of the Norwegian University of Science and Technology (NTNU), member of the Visiting Panel for Research at the Educational Testing Service (ETS) in Princeton, expert member of the PISA (2022) Questionnaire Framework group, appointed by ETS and OECD (2014–2023). She has advised on the implementation of formative assessment programs in India, South Africa, Norway, and the Emirates and carried out policy work for UNESCO/OECD and the Norwegian Ministry of Education Norway. Therese has a presence on LinkedIn, ResearchGate, [Academia.edu](https://www.academia.edu/), and Twitter: @TNHopfenbeck.

Nataliya Ivankova, PhD, MPH, is Professor in the School of Health Professions at the University of Alabama at Birmingham (UAB). As an applied research methodologist working at the intersection of mixed methods, qualitative, community-based, action, and translational research, she is internationally recognized for her empirical and methodological publications. She shares her research expertise through teaching mixed methods and qualitative research courses, conducting workshops and guest lectures, mentoring doctoral students and junior faculty, and serving as key personnel on funded research projects. At UAB, she directs an online graduate certificate program in *Applications of Mixed Methods Research* and oversees the design and analytical aspects of qualitative and mixed methods studies through the Center for Health Informatics for Patient Safety and Quality. She is a founding Coeditor of the *Mixed Methods Research Series* (Sage) and serves as an Associate Editor for the *Journal of Mixed Methods Research*.

Professor Jahnke is Director of Toi Kura Centre for Maori & Indigenous Education. She was the 2019 inaugural Toi o Te Wananga Fellow. Professor Jahnke holds professional qualifications in education and is cofounder and immediate past Chair of the Indigenous Peoples of the Pacific Special Interest Group of the American Education Research Association (AERA). She currently serves on the AERA Executive Committee. She was a member of the Social & Human Sciences Sub Commission of the NZ National Commission for UNESCO, the NZ Bioethics Council, the NZ Ethics Committee on Assisted Reproduction Technology, and Chair of NZ Health Research Council Ethics Committee. She is currently Cochair of the Aotearoa Research Ethics Board and a Fulbright Scholar.

Berit Karseth, PhD, is Professor at the University of Oslo, Department of Education. Karseth's main research and publications lie in the field of education policy, reforms, and curriculum studies. She has edited four books and written several journal articles and book chapters in both Norwegian and English. Her most recent publications in English include articles published in the *Journal of Education Policy*, *Scandinavian Journal of Educational Research*, *Journal of Curriculum Studies*, and *European Educational Research Journal*. Karseth was the elected dean of the Faculty of Educational Sciences at the University of Oslo 2013–2016 and is currently in the leadership team of the research group Curriculum studies, educational leadership, and governance (CLEG) at the same institution.

Dr. Kenneth Leithwood is Emeritus Professor at OISE/University of Toronto and an honorary professor at the University College London and the University of Nottingham. His research and writing is about school leadership, educational policy, and organizational change. He has published extensively on these topics. For example, his most recent books include *Leadership Development on a Large Scale: Lessons for Long-term Success* (2018, Corwin), *How School Leaders Contribute to Student Success* (2017, Springer), and *Linking Leadership to Student Learning* (2012, Jossey Bass). Professor Leithwood is the inaugural recipient of the University of Toronto's *Impact on Public Policy* award, AERA (2011) *Outstanding Leadership Researcher Award*, the 2012 *Roald F. Campbell Lifetime Achievement Award* from the University Council for Educational Administration, and the Ontario Principals' Council *Outstanding Educator of the Year* award for 2017. He is a *Fellow of the Royal Society of Canada*. A recently published bibliometric analysis found that Dr. Leithwood was the most frequently cited, highest impact educational leadership researcher in the world.¹ Research.com's 2022 Ranking of the Top 1000 Scientists in the area of Social Sciences and Humanities ranked Dr. Leithwood 70th in the world and 7th in Canada.

Xiufeng Liu is a Professor of Science Education at State University of New York, Buffalo, and a Fellow of the American Association for the Advancement of Science (AAAS). He obtained his PhD from the University of British Columbia in 1993. Before his current position, he taught high school chemistry in China, and was a tenured faculty member at St. Francis Xavier University and University of Prince Edward Island, both in Canada. From September 2020 to August 2022, he served as a program director in the Division of Research on Learning of the National Science Foundation. Dr. Liu conducts research on measurement and evaluation of STEM education and student learning of cross-cutting concepts of matter and energy. Dr. Liu is currently a Coeditor-in-chief for the journal *Disciplinary and International Science Education Research* (Springer) and an Associate Editor for the *Journal of Research in Science Teaching*, a premier journal in science education.

Margie Maaka is a Professor of Education at the University of Hawai'i at Mānoa. Her PhD is in educational psychology. She also holds professional qualifications in education from the University of Waikato and Hamilton Teachers College. She is cofounder and current Program Chair of the Indigenous Peoples of the Pacific Special Interest Group (SIG) of the American Educational Research Association (AERA). From 2017 to 2020, she served as a member of the AERA Executive Council and Chair of the SIG Executive Committee. Before that (2014–2017), Professor Maaka served as a member of the SIG Executive Committee. She has also served as a member of the Ngā Pae o te Māramatanga Center of Research Excellence International Research Advisory Panel. Her research on community-based educational renewal saw her recognized as a national scholar with the Goodlad Institute for Educational Renewal. As Cochair of the Sovereign Councils of the Hawaiian Homelands Assembly's Committee on Education, she prepared educators and educational leaders for public schools in the Hawaiian Home Lands Trust communities. Currently, Professor Maaka is committed to the preparation of indigenous educational leaders in higher education. Her research interests include community partnerships, educational psychology/indigenous educational psychology, indigenous development and advancement, educational policy, multiliteracies, and language and cognitive development.

Diane Mayer is Professor Emerita at the University of Oxford. Her research and scholarship focus on teacher education and early career teaching, examining issues associated with the policy and practice of teachers' work and teacher education.

Daniel McCaffrey is the Associate Vice President of Psychometric Analysis and Research in the Research and Measurement Science unit of the Research and Development division at ETS. Dan's research interests include the evaluation of artificial intelligence scoring of constructed responses, developing tools and methods for causal modeling, evaluating the psychometric properties of student achievement growth measures derived from annual test scores, and methods to account for measurement error in secondary data analysis. Dan received his PhD in Statistics from North Carolina State University in 1991.

Judy Parr is Professor Emerita at the University of Auckland, Faculty of Education, where she was the founding Head of the School of Curriculum and Pedagogy. A psychologist, Dr. Parr's research program is located broadly within improvement science. Her expertise is in literacy, specifically writing and its development, encompassing instructional issues like teacher knowledge and practice and the assessment of writing. Much research has been collaborative, with colleagues and practitioners within major national projects for school improvement aimed at raising achievement in literacy and, internationally, as part of funded large-scale research projects, for example in Canada and Norway. Dr. Parr has published widely in the areas of literacy, assessment, and professional learning.

Jeong-eun Rhee is a Professor of Education, Long Island University, Post, New York. Born and raised in Seoul, Korea, she earned her bachelor's degree in Educational Psychology from Ewha Women's University. In 1992, she came to the US as an international student and received an MA in Educational Psychology from West Virginia University and a PhD in Educational Policy and Leadership from the Ohio State University. As an interdisciplinary cultural researcher and educator, her recent work focuses on developing and supporting transnational, intergenerational, and decolonial feminist knowledge projects in/through antioppressive education. She recently published *Decolonial Feminist Research: Haunting, Rememory, and Mothers*, which received an honorable mention for the 2022 Qualitative Book Award of International Congress of Qualitative Inquiry.

Fazal Rizvi is an Emeritus Professor of Global Studies in Education at the University of Melbourne, as well as at the University of Illinois at Urbana-Champaign. He is also a Visiting Professor at the Universities of Turku in Finland and Pretoria in South Africa. He has written extensively on issues of identity and culture in transnational contexts, globalization and education policy, and Australia-Asia relations. He has published widely and his book, coauthored with Bob Lingard, *Globalizing Education Policy* (Routledge, 2010), is used widely in courses around the world. A sequel to this book, *Reimagining Globalization and Education* (Routledge, 2022), has been published recently. Fazal is currently researching educational reform in Bhutan. He is a Fellow of the Australian Academy of the Social Sciences, a past Editor of the journal, *Discourse: Studies in Cultural Politics of Education*, and a past President of the Australian Association of Research in Education.

Theresa Rogers is Professor of Language and Literacy Education at the University of British Columbia. Her research interests include youth arts, media and critical literacies, adolescent literature, and teacher education in literacy. Most recently she published "Youth Activism through Critical Arts, Transmedia, and Multiliteracies" in the *Oxford Research Encyclopedia*. She is author of the book, *Youth, Critical Literacies and Civic Engagement: Arts, Media and Literacy in the lives of adolescents* (Routledge) and numerous articles in scholarly journals such as *Literacy Research: Theory, Method and Practice*, *Reading Research Quarterly*, *Pedagogies*, *Language Arts*, *Children's Literature in Education* and *Journal of Literacy Research*. See: <https://ubc.academia.edu/TheresaRogers>.

Professor Chika Sehoole is a Professor of Higher Education and the Dean of the Faculty of Education at the University of Pretoria. He obtained his PhD at the University of the Witwatersrand, Johannesburg, in December 2002. In 2003/4 he was a visiting Rockefeller postdoctoral fellow at the Centre for African Studies at the University of Illinois in Urbana Champaign. In 2005/06 he was a New Century Fulbright Fellow, again, at the same university. His research interests are in the areas of higher education policy, internationalization of higher education, higher education in Africa, and teacher education. He has served in several international research projects focusing on higher education and providing expertise from the South African and African perspectives. In 2013–2017 he served as the Chairperson of the Board of the African Network for Internationalisation of Education (ANIE). He currently serves as the chairperson of the Education Deans' Forum of South Africa. He has published a singled authored book titled "Democratising higher education policy, constraints of reform in post-apartheid South Africa" by (Routledge); three edited scholarly books on higher education and more than 40 articles in journal articles, book chapters, and popular media.

Roland Sintos Coloma is a tenured Full Professor of Teacher Education at Wayne State University in Detroit, Michigan. A scholar of history, cultural studies, and education, his research addresses critical questions of race, gender, and sexuality from transnational and intersectional perspectives. His publications include *Asian Canadian Studies Reader* (2017), *Filipinos in Canada: Disturbing Invisibility* (2012), and *Postcolonial Challenges in Education* (2009). His articles have been published in top-ranked peer-reviewed journals, including *Curriculum Inquiry*, *Discourse: Studies in the Cultural Politics of Education*, *Educational Studies*, *Educational Theory*, *History of Education Quarterly*, *International Journal of Qualitative Studies in Education*, *Paedagogica Historica*, and *Race Ethnicity and Education*. He has successfully garnered over \$2 million of external funding from federal, education, and nonprofit agencies, including the US Department of Education, National Education Association, Spencer Foundation, and Schultz Family Foundation as part of the Bill & Melinda Gates Foundation's Grand Economic Challenges. Roland has served in various university leadership roles as an assistant dean, department chair, graduate coordinator, and center codirector. He was president of the American Educational Studies Association (2018–19), editor of the *Educational Studies* journal (2014–17), and program cochair of Division G (Social Context of Education) in the American Educational Research Association (AERA). He received the 2017 Distinguished Scholar Award from the AERA Research on the Education of Asian Pacific Americans SIG and the 2015 Article of the Year Award from the AERA Queer Studies and Education SIG. In 2020, he was appointed to the Governor of Michigan's statewide Asian Pacific American Affairs Commission. Born in the Philippines and raised in California, he completed his PhD in Cultural Studies in Education and Minor in African American and African Studies from The Ohio State University in 2004.

Roger Slee is the Founding Editor of *The International Journal of Inclusive Education* and *The Journal of Disability Studies in Education*. A former Deputy Director-General of Education in Queensland, Australia, he has advised governments on inclusive education policy and practice. His published books include: *The Irregular School*; *Inclusive Education Isn't Dead, It Just Smells Funny*; and *Ethics and Inclusive Education: Disability, Schooling & Justice* (with Gordon Tait). Roger was commissioned by the UNESCO to write the scoping paper for the 2020 Global Education Monitoring Report, *Inclusion and Education*. Roger also held the Chair of Inclusive Education at the Institute of Education, London, and is now the Diamond Jubilee Professor of Disability & Inclusion in the School of Sociology & Social Policy at the University of Leeds.

Ninni Wahlström is a Professor of Education at Linnæus University, Sweden. Her current research focuses on transnational and national policy discourses and their implications for national curriculum and classroom teaching from a perspective of curriculum theory and educational philosophy. Most recent publications are "School and democratic hope: the school as a space for civic literacy" in *European Educational Research Journal* (2022) and Wahlström (Ed.) *Equity, Teaching Practice and the Curriculum*, Routledge (2022).

Lei Wang is Professor and PHD advisor of the Institute of Chemical Education, the College of Chemistry in Beijing Normal University (BNU). She is also the member of Teaching Steering Committee on Basic Education of Ministry of Education of China and the director of its branch Committee on Secondary Chemistry Education, the director assistant of Faculty of Education of BNU, vice director of the Institute of Science Education of BNU, and Chairman of the Chemistry Education Committee of the Chinese Chemical Society. She is one of the chief experts in developing the *Secondary School Chemistry Curriculum Standards* of MOE. She works as the chief editor of high school chemistry textbooks (Shandong Science and Technology Press, 2004 and 2019 editions) and junior high school chemistry project-based learning textbooks (Shanxi Education Press, 2018 edition). She achieved the first prize of the National Basic Education Teaching Achievement Award, the second prize of the National Higher Education Teaching Achievement Award, and the BAOGANG Education Outstanding Teacher Award.

Everard Weber is a retired professor. He has worked in the field of education for more than 40 years. Currently he is a research associate at the University of Johannesburg (UJ) and an academic advisor in the Future Professors Programme (FPP) at UJ. He studied African Languages and History at the University of Cape Town and Comparative and International Education at Harvard University. In South Africa he has worked at Crestway High School in Cape Town, the University of the Witwatersrand, and the University of Pretoria. A recent book is *A home away from home: a community of international and South African university students*. The FPP is a government-sponsored initiative that seeks to develop the next generation of professors and academic leaders in all disciplines, across all universities in South Africa. He is in addition presently conducting fieldwork on curriculum change in South African higher education with Professor Shireen Motala and Dr. Venise Joubert at UJ. This project is grounded in the history of southern Africa and hopes to contribute to the scholarship of postcolonialism.

Ian A.G. Wilkinson is Professor in the Department of Teaching and Learning at The Ohio State University and Honorary Professor in the School of Curriculum and Pedagogy at the University of Auckland, Aotearoa/New Zealand. He has a background in educational psychology with special interests in cognition, instruction, and research methodology as they relate to the study of literacy. He served as coauthor of the influential report, *Becoming a Nation of Readers* (National Academy of Education, 1985). He was Co-Editor of *Reading Research Quarterly* from 2006 to 2012 and was inducted into the Reading Hall of Fame in 2021. His research examines the impact of classroom discussion and dialogue on students' reading comprehension and argument literacy and the implications for professional development of teachers. Recently he coauthored books include *The Most Reasonable Answer: Helping Students Build Better Arguments Together* and *Quality Talk About Text: Discussion Practices for Talking and Thinking About Text*.

David B. Yaden, Jr., PhD, is the *Jewell M. Lewis Endowed Distinguished Professor of Literacy* in the Department of Teaching, Learning and Sociocultural Studies at the University of Arizona. Prior to his present position at the University of Arizona, he held appointments at Emory University, the University of Houston, and the University of Southern California. He served as Co-Editor of the *Journal of Literacy Research*, one of the premier research journals in the field of literacy studies, and was a Principal Investigator in the federally funded Center for the Improvement of Early Reading Achievement (CIERA) where he implemented an early literacy curriculum for linguistically diverse preschoolers in inner-city Los Angeles. He also directed a statewide consortium of researchers from Arizona's major universities in the evaluation of the state's early childhood initiative to evaluate health, developmental, and educational factors contributing to school readiness. His research interests and specializations include developmental issues in early childhood education, the acquisition of literacy and biliteracy in young emergent bilingual children, family literacy, theories of reading disability, microgenetic research design, and the application of complex adaptive systems theory to growth in reading and writing.

Volume 7: Approaches to the Curriculum and Its Politics

Berit Karseth and Ninni Wahlström

© 2023 Elsevier Ltd. All rights reserved.

Introduction

In this, we introduce the themes and contributions that form the basis of the volume “Approaches to curriculum and its politics” within the 4th edition of the *International Encyclopedia of Education*. A common theme that binds these chapters together is unraveling the importance of the curriculum for different aspects and perspectives on education in general and in schools and preschools, in particular. Furthermore, two areas recur across the chapters: the curriculum as part of a framework for the governance of schools and the curriculum as an arena for competing perspectives on knowledge.

The definition and meaning of the term “curriculum” have been the cause of lengthy discussions. According to the *Oxford English Dictionary*, the term curriculum means “a regular course of study or training, as at a school or university”. However, as early as the beginning of the 20th century, John Dewey (among others) considered such a definition too narrow, although he never tried to formulate a new definition. Instead, he highlighted the gap between the child and the curriculum in a text that employed this exact title (Dewey, 1976). Highlighting young children’s interests and activities with respect to the formal course of study was an effective way of illustrating the need for some kind of transformative pedagogical activity that would enable a connection between the two parties (Jackson, 1992). Dewey posed two questions that underpinned all curriculum making: “What do we want to do, and why?” and “How can we do it?” However, these questions cannot be answered through the text of the curriculum alone, even if they constitute an important basis. Rather, they should be understood from a broader perspective that includes the actual institutional and organizational frameworks that shape the practice of the school (Westbury, 2008).

As Apple (2008) noted, the choices and emphases made in the field of curricula also raise ethical and political issues. The curriculum is not only a “course of study,” as it is also a site of conflict about what kind of knowledge content should be selected and included in the curriculum and how teaching and learning should be assessed. Moreover, how curricula are selected, taught, and evaluated cannot be understood as isolated phenomena in the field of education. Instead, these activities need to be understood as relational to the society in which they exist and to prevailing power relations (Apple, 2008). Based on such a perspective, Pinar’s understanding of curriculum as “an extraordinarily complicated conversation” in which we “choose what to remember about the past, what to believe about the present, what to hope for, and fear about the future” offers a more multidimensional meaning of the concept of curriculum than simply “a course” to be followed (Pinar, 2008). Hence, the *understanding* of a curriculum as a contextualized and experienced phenomenon is an important aspect of curriculum studies (Jung and Pinar, 2016). Drawing on Basil Bernstein (1975), the curriculum can be viewed as being included in a broader message system of education, distinguishing between the curriculum as representing valid knowledge, pedagogy as the valid transmission of knowledge, and evaluation as the valid realization of knowledge (Wyse et al., 2016). In this way, the selection of knowledge, the teaching of the subject content, and the assessment of student knowledge can be understood as constituting core interests in the field of curriculum research.

A critical curriculum theory approach comprises two questions: what is included in the curriculum and what is excluded. For this purpose, the curriculum definition that guides this section is what the child and the student “have an opportunity to learn” through education, which emphasizes the continuum between the curriculum and teaching (Cherryholmes, 1988, p. 133). This definition of what the students have an opportunity to learn acknowledges the curriculum as a guideline for planning and evaluation. This definition also includes what students learn from the school structure and organization, from their peers, and from what is excluded from the discourse of the teaching content. In the following, this broad understanding of critical curriculum theory research guided the selection of themes that constitute the basis of this section. The chapters in this section are largely inspired by studies that are characterized by a critical reading of different approaches to curricula and their relationships with politics and practice.

The chapters in this volume are situated in different national contexts and regions. Despite globalization, the distinctiveness of national history and culture can play an important role in how curricula are structured and designed (Deng et al., 2022; Tröhler, 2014), enacted in classrooms, and recontextualized in pedagogical practices (Ensor, 2015; Schulte, 2018). On the one hand, acknowledgment of the situatedness of the curriculum (as well as curriculum research) can be perceived as an obstacle to comparative research. On the other hand, these differences and particularities invite us to learn about other systems, helping us understand our own curriculum history and system of reasoning.

The chapters in the first section examine aspects of curriculum governance and global education policy. Curriculum reforms are viewed from both historical and contemporary approaches, and they reflect specific purposes and conditions that change over time. As a modern invention, various actors set the agenda and formulate purposes with regard to given circumstances. The historical and theoretical roots of the dilemma between curricular centralization and teacher autonomy are discussed in this section by drawing attention to the complexity of curriculum governance, which is linked to every aspect of the education system. Moreover, it relates to curriculum models, visions of what is relevant to learn, and implications for the role and agency of both teachers and students. In addition, the processes of decentralization and centralization are discussed. Furthermore, the chapters reveal the impact of current transnational curriculum models and examine the discourse pertaining to the position of 21st-century skills in the curriculum. This represents a manifestation of the concerns of diverse stakeholders in society about the current relevance of the formal education curriculum in these times of rapid changes in society. In one of the contributions, an argument is made that the logic of current transnational curriculum models is based on learning outcomes that under stipulate curriculum content. This places new burdens

on all teachers, especially those in developing countries. From a different empirical point of departure, another chapter demonstrates how global curriculum models are recontextualized according to traditions and dynamics that exist within an educational system. This analysis highlights the complex, ever-changing dynamics that underlie contemporary curricular policies. The section also presents critical frameworks for analyzing curriculum reforms and offers different theoretical lenses to unpack curriculum reforms beyond global trends.

The second theme is termed “curriculum theory,” which includes contemporary trends of two topical curriculum discussions: understanding the curriculum as part of the governance of education and arguments for different kinds of knowledge approaches that should underpin curriculum. These trends can be described as displacements from new public management to more pronounced multilevel governance (often in terms of networks) and from an unproblematic approach to knowledge to a discussion of knowledge that focuses on the relationships between humans and the “real” world. The topic of realism is followed up in a chapter that focuses on a discussion of the philosophy of critical realism. Furthermore, the notion of “critical” in curriculum theory is discussed in terms of “new materialism,” which goes beyond divisions into subjects and objects. It is argued in this discussion that critical theory brings into view an agential notion to resist the seemingly “normal” in educational practices.

From a historical perspective, the development of curriculum studies as an educational subdiscipline is reconstructed, and three models of curriculum theory on three different levels of theoretical abstractions are outlined. From another historical angle, an analysis of world systems suggests the need for a reorganization of the social sciences that breaks with the development of the social sciences as knowledge disciplines in the historical trajectory of the capitalist world system. Finally, it is argued that the theories of new institutionalism, especially its latest model of discursive institutionalism, constitute a vital theoretical starting point for analyzing curriculum change in a globalized world.

In the next section of curriculum research, the focus is on curriculum making at the local school level, which entails deliberative decision-making at the planning stage and in the work within the classroom. It is argued that curriculum making is dependent upon teacher agency, which is strengthened by meaningful curriculum making as a social practice. The words we choose to describe the actions (or positions) that teachers take in relation to the curriculum matter because they reveal how we consider teachers as professionals and what we perceive (or expect) their role to be with respect to curriculum policy directives. Deliberative decision-making requires the use of theory to illuminate and interpret specific issues and problems and involves fundamental questions related to what teachers do and think. Hence, curriculum making constitutes an important part of teacher education.

Innovative pedagogy and curricula should be understood as accommodating divergent interpretations and actions that are negotiated and exercised as part of the pedagogical processes of interpreting the curriculum and transforming it into teaching at the school level. Moreover, teachers, children, and students should be involved in curriculum making, as this can also be understood as a learning activity. Accordingly, the ontologies, theories, and ideas that enable children to participate in local curriculum making are presented and discussed. In many early childhood curricula, children’s interests are purported to be central. Thus, this subsection includes definitions of the term “children’s interests” and ways in which these can inform approaches to interest-related curricula. At the other end of the age scale, curriculum making in higher education is explored from the perspective of activity theory, emphasizing academics as actors. Shifting the focus to a macro level, curriculum development can also be understood as a specific part of the broader process of curriculum making. Currently, it is argued that it is often more appropriate to speak about curriculum revisions or reviews rather than curriculum reforms.

Under the title “Curriculum design and curriculum innovations,” the subsequent set of chapters highlights new and emerging approaches. There are different approaches to curriculum design (such as instrumental and deliberative), and it is argued that an approach that emphasizes the important role of research in the process is preferable. Common themes in many of the chapters are an emphasis on the learner and questions about how to develop a learning environment that enhances student involvement in decision-making processes. In particular, investment in bottom-up initiatives is necessary to successfully implement a curriculum design that invites cooperation when designing a curriculum. Moreover, the distinction between the cocreation of the curriculum and cocreation *in* the curriculum is described. Curriculum changes are also affected by how school buildings are designed and used. School architecture is not only defined by the architect’s pen; it is created through policies and pedagogies, as well as teachers’ and students’ everyday use of space.

Within the theme of “Curriculum, school subjects, and Didaktik,” one of the chapters provides an overview of the theoretical and practical domains constituted by European Continental Pedagogy, emphasizing key aspects of its history and theory. Here, Didaktik is discussed in terms of the relationships illustrated through the “didactic triangle,” which combines the educator, the *educand* (the one being educated), and the world (the selection of content). In another chapter, Didaktik is contextualized as tightly connected to the curriculum and Bildung in a European continental (German-speaking) tradition. These three concepts are presented in their origins from a German discourse on education and in relation to an Anglo-American understanding of curricula. It is also argued that the three concepts have changed in certain ways due to competence-based curricula and standardized testing. It is apparent that different orientations of the view of knowledge have consequences in terms of schools’ selection of teaching content and the organization of teaching. Generic competencies, as highlighted in the OECD project “The Future of Education and Skills: Education 2030,” can contribute to transforming education policy in national arenas. The transnational perspective of the OECD and international knowledge tests results in a discussion of how the notion of competence varies across contexts and over time. In another text, the concept of competence is explored, including its role in a differentiated curriculum, the connection between competence and assessment, the relationship between competence and standards, and how this relates to the increasing importance of accountability in education systems. Within a closely related area to the discourse on competencies, the question of how an interdisciplinary approach can be understood and applied in different countries is raised, in addition to why interdisciplinarity should be promoted in basic education.

In school subjects, tensions often arise between different perspectives when selecting teaching content. The curriculum of the school subject history is discussed in relation to human activity throughout history, which significantly influences the climate and ecosystem on the earth. However, turning the subject of history in the direction of a deepened understanding of the development of climate change could challenge the current understanding of the body of knowledge that constitutes the school subject of history. In addition, new emphases for social studies teaching are outlined, where students examine inequitable power relations as a way of deepening their understanding of society. Another field of tension is explored in the literacy curriculum. Here, one trend is toward expanding and pluralizing the scholarly understanding of literacy, while another is toward curriculum and policy focused on measurable units and standardization. The subject of science is discussed in terms of always being a representation of scientific content rather than being a scientific content in itself. This is due to pedagogical considerations that inevitably involve certain selections and simplifications of the teaching content. Another field of tension that is actualized is between public education and supplementary curriculum out of schooling provided by educational business industries (referred to as shadow education).

In the section of “Lived curriculum,” the intersection between curriculum implementation and making is explored and problematized. While the curriculum generally comprises implementing governing regulations, curriculum making is about teachers educating learners in a local context. In the intersection between these arenas, issues pertaining to the enactment of teacher knowledge in context, competing stories of schools, and alternate versions of teacher communities emerge. The boundaries between school and life outside school are also challenged in terms of “living schools,” which reflect the creativity inherited from the life process itself. The significance of teachers and their curriculum making is clearly noticeable when on the front line, such as when facing structural inequalities in educational systems or challenges from the impacts of COVID-19. The process of individual and collective meaning making constitutes the core of curriculum enactment, which is a process that can adopt many different forms and adapt to different local situations. For example, the concept of identity options foregrounds the need to value learners’ cultural, linguistic, and epistemic resources in curriculum making. This has also promoted the consideration of how curricula are lived or experienced by learners and how this can affect their sense of self in the world.

The last section in this volume is entitled “Curriculum, democracy, and inclusion,” which consists of five chapters that share the common concern of education in the context of democracy. The global education policy of the United Nations’ Education for Sustainable Development is examined, and it is suggested that the common good should be included in a curriculum theory that aims to critically explore the curriculum processes involved.

It is important for the well-being of society that the younger generation is provided with opportunities to understand the possibilities that digital technology brings to sociopolitical participation as well as the threats it can pose to upholding the core values of social justice and democracy. Ideas around democracy and younger children have focused on children’s rights rather than children’s participation in democratic processes. Accordingly, one of the chapters contains a discussion on the curricular potential for democracy in early childhood, which would allow them to develop their own “voice” and actively participate in democratic processes.

The curriculum sends powerful messages to students about whose voices and perspectives are valued by society at large. Hence, as a reflection of dominant groups, the curriculum functions to marginalize LGBTQ+ students unless educators design an inclusive curriculum based on equity, democratic governance, and social justice.

The curriculum and inclusive education relate to children with diverse abilities and preferences having access to the curriculum and represent two tightly wound initiatives. No system can claim to serve the public unless it is accessible to all its members. The Universal Design for Learning framework is one approach for ensuring that education can be accessible to all participants in an educational setting. Although Universal Design for Learning is a promising traveling concept in many ways, it does not mean education for all, as some forms of disabilities continue to be excluded from their national curriculum.

Introduction

Discussions of curriculum, and proposals for curriculum change, usually swing between two poles: between a 'traditional' model based on school subjects and their content, driven predominantly by the teacher, and a 'progressive' model which favors weaker subject boundaries, thematic organization, looser specification of the content to be learnt, promoting initiative and autonomy on the part of learners. There are a number of alternative terms for these two polar models, but we will use these until we introduce a more analytical classification in the discussion below.

These are of course ideal types, and curricula have historically varied widely in the way these have been implemented, with hybrid sub-types readily discernible, though usually with one or other predominating. Disillusionment with the one seems to trigger an enthusiasm for the other. This has recently been given renewed impetus by international tests like TIMSS and PIRLS which have inevitably led to invidious comparisons between 'winning' and 'losing' schooling systems. The finger of blame is most often pointed at the curriculum model, which has led in turn to political and lay enthusiasm for supposedly 'winning' models, like the 'Finnish model' for example. In practice, curriculum systems vary widely. One key reason for this lies with the embeddedness of educational practices which often persist in their old tried and tested manner despite the overlay of a new system. Newer prescripts then become grafted onto, absorbed by, or re-interpreted in the light of established practices. This gives rise to hybrids, which at best work fairly well or, at worst, fall victim to incompatible design logics which undermine each other. The resulting failure then gives rise to the next cyclical swing.

The principal difference between curriculum reform in developed as against developing countries used to be more distinctive than it is now. In the past, the Anglo-American developed countries together with those of Europe and Asia had reasonably distinct national curriculum/pedagogical traditions – the early specializing, streamed system in England as against the late specializing quasi-system in the USA, with autonomy for the different states to set their own criteria; the *didaktik/bildung* wellspring of the Germanic and Nordic countries; the Confucian system in China and the East Asian countries to mention only a few distinct traditions. Also, European countries like France and Germany have long experience with national curricula, compared to countries like the USA where federal control of the curriculum is still strong. More latterly, the global ecumenism of TIMSS and the agencies pursuing a globalizing agenda – like the IEA, UNESCO, OECD – have constructed a marketplace for national comparisons which, despite claims of a decades-long convergence of curricula (McEneaney and Meyer, 2000), has given this convergence accelerated impetus. Convergences are now everywhere discernible, at least at the symbolic and policy level. Nevertheless, the lineaments of the national traditions of the developed countries are still readily evident (Tröhler, 2016).

Many developing countries, particularly those with a colonial past, have schooling systems which bear a distinct imprint of their colonial pasts. To take one example, South Africa's schooling system owes something to its English colonial roots and something to the Germanic roots brought to South Africa by the Dutch colonists from whence sprang apartheid ideology and 'black' education. The once-black schooling system, only partly transformed, still today educates about 80% of the school-going population in what van den Berg and Louw (2006) call 'schools for the poor'. The 80% resemble the schools in many developing countries.

Recent curriculum reform in the developing world¹

A common set of attributes is to be found in the curriculum and pedagogy of many developing countries: the lessons are run by the teacher who does most of the talking; the learners are passive unless asked to respond; the response is often in the form of collective chanting; the learners copy material into their books, and are drilled on the material (Schweisfurth, 2011; see also Carnoy et al., 2012). The pace of the lesson is usually slow, often repetitive, so that curriculum coverage is limited. When learners proceed to

¹This section and ones that follow draw on Hoadley (2018); Muller and Hoadley (2019).

the next grade, they are rarely well prepared to encounter the more complex material, and knowledge gaps are frequent, posing a hurdle to progression especially in conceptually-rich subjects like science and mathematics.

Two other features of the pedagogy are worth noting. First, learners engage curriculum content orally far more than they do textually, in either reading or written form. Books, or other forms of text, are not a regular feature of many developing country classrooms. Secondly, teachers engage the whole class far more often than they do individual learners. Since there is little explicit marking out of individual performances, performance level is a collective affair, which invariably means regression to a fairly low common denominator. Small wonder then that empirical studies have found a persistent pattern of low performance outcomes (Glewwe and Muralidharan, 2015; Pritchett and Beatty, 2012). It is this pattern that curriculum reform has sought to reverse.

Perhaps because this pattern must have seemed to observers to be a version of traditionalism, the majority of proposals for reform were a variant of progressive curriculum and pedagogy, an emphasis on relevance to both the worlds of the learners and the world of work, and a thematically driven curriculum with weakened boundaries between subjects. This model was carried to the developing world in the 1980s first by the international lenders as part of structural adjustment packages, and later with more zeal by international aid organizations with the UNESCO 'Education for All' World Declaration a high-water mark for globalizing progressivism (UNESCO, 1990).

By the early 2000s the pendulum was swinging again, and donor and international aid agencies were transferring allegiance to a model of generic skills and competencies said to be essential for the rapidly changing world of work in the 21st century. Superficially akin to progressivism – they both promoted the initiative of the learner, interdisciplinarity and relevance, for example – these features mask a more fundamental shift in the social logic of the curriculum model which marks a relative departure from progressivism. We discuss this further below.

Progressivism of one form or another has, until recently at least, remained popular in developing countries. The longevity of the popularity of progressivism has been variably assigned, but at least one feature has been the elision of education and politics: political progressivism and educational progressivism have been assumed to be two sides of the same coin, such that to be politically progressive meant to be educationally progressive. To question the one was to question the other. Small wonder that post-colonial elites have found it easy to persuade their followers that this was the way to go.

The impact of the reforms, however, has been hard to judge. The effects on student outcomes have been disappointing, and traditional practices have persisted to a greater or lesser extent. In almost all cases, evaluations have noted the observance of the outward forms of progressivism but no substantive uptake of the deeper social logic of the model. What is evident in this recurrent pattern is the recruitment of the forms of progressive pedagogy, like group work for example, to the collectivizing practices of a particular form of traditional pedagogy. This is ascribed by some to traditional cultural practices within which the teachers remain embedded (Schweisfurth, 2011).

Interesting reports from some developed countries also signal how curriculum reforms graft imperfectly onto long established traditional practices. In Singapore, for example, the pedagogy has remained relatively immune to progressive influence despite government embrace of progressive policy prescriptions from the OECD. What makes Singapore interesting is the fact that although the government has made concerted efforts to promote features of progressivism, through the introduction of programmes like 'Innovation and Enterprise' in 2004, and 'Teach Less, Learn More' in 2005, the schools have retained 'a strong focus on direct instruction and traditional pedagogic practices' (Deng and Gopinathan, 2016, p. 460). They also continue to perform near the top of the ladder on the OECD's PISA test. Interesting too is the case of late-industrializing Finland, where one principal cause of their pre-eminence in PISA outcomes has been ascribed to 'a hierarchical and traditional schooling climate' (Sahlgren, 2015, p. iii), and their more recent fall in performance to their belated shift to progressive learner centered classroom methods.

Our focus in this chapter is, however, on curriculum reform in developing contexts, where there have been few unambiguously successful cases of progressive curriculum reform. A form of traditional practice continues to hold sway, one that is more or less effective. Indeed, where there have been demonstrable achievement effects in the developing world, as in Cuba (Carnoy and Marshall, 2005) and Ecuador, and to a lesser degree in Peru and Chile (Schneider et al., 2017), these have coincided with curriculum reforms that look very like a stringent version of traditional pedagogy – with 'a strong focus on direct instruction and traditional pedagogic practices' (Carnoy and Marshall, 2005, p. 460). We are left unclear as to whether the failure of progressive reforms is because of failures of implementation, low dosage, sedimented cultural practices, or some other factor. What has not so far been examined is the social logic of progressivism and its difference from that of traditionalism. We examine this below.

The emergence of transnational curriculum reform discourse

In the shift from the Millennium Development Goals (for the period 2000 to 2015) to the 'Sustainable Development Goals' (for 2015 to 2030; see UN, 2015), the shift toward generic skills was sustained but with an additional education reform discourse around 'learning outcomes' (Verger et al., 2018). In 2018 the World Bank declared a 'global learning crisis' (World Bank, 2018). Despite impressive achievements in access to education across nations, this had not translated into increased levels of learning. Wide-spread testing using the Early Grade Reading Assessment had shown that across developing countries learners were leaving school barely able to read and write in the language of instruction despite completing six years of primary education (World Bank, 2018). Gone were ubiquitous references to learner-centered pedagogies.

What followed was a 'new learning agenda', and an emphasis on learning and learning outcomes evident in academic literature (Verger et al., 2018) and also in key reports of multilateral and donor organizations and NGOs (UNESCO, 2017/2018). The World Bank attributed one of the central reasons for the learning crisis to education systems in the developing world having little evidence around who was learning and who was not. Consequently, in the period after 2015, there was a shift to transnational measurement of basic numeracy and literacy and the establishment of the Global Alliance to Monitor Learning (GAML) to develop methodological tools and standards to 'ensure global comparability among indicators related to learning outcomes' (UNESCO, 2016).

Criticism of the new learning agenda focused on the lack of an explicit theory of learning (Tikly, 2017), 'distanced from discussion of pedagogy as debate and focused mainly on questions relating to the outcomes of learning – which outcomes we should care about and how can they be measured' (Barrett et al., 2015, p. 231). In October 2020, the GAML published a set of 'proficiency frameworks' for reading and mathematics, with 144 pages of domains, constructs, subconstructs and global proficiency descriptors for mathematics Grades 1 to 9 (GAML, 2020). This drive for ever greater specificity is the fate of outcomes-specified curricula that refrain from extensive content specification. As Knight (2001, p. 373) remarked, 'Clarification leads to complication which is why lists of outcomes grow like mold and become unwieldy'. This too was the consequence of South Africa's experimentation with a radical form of outcomes-based curriculum reform, as we briefly show below.

One response to the focus on learning outcomes has been an assertion of the need to go beyond narrow skills statements of learning to incorporate '21st century skills'. Frameworks for these sets of skills are proliferating (Global Partnership for Education, 2020). The notion of 'skill' in these documents is a relatively common-sensical one, with none of the nuance to be found in more conceptual analyses of skill like that of Winch (2012). Some argue that these skills can't be prised away from the transmission of subject content knowledge: 'While it is hard to argue against the importance of creativity, communication, collaboration and critical thinking, one has to create, communicate, collaborate and think critically about *something*' (Thornton, 2020, p. 2). Nevertheless, considerable effort is being expended in trying to work out *how* they are taught, with such efforts often framed in the abstract (Taylor et al., 2020).

The OECD has recently produced their own iteration of '21st century skills' in their 2030 Learning Framework (OECD, 2018; 2019a) and 'Learning Compass' (OECD, 2019b) which includes a range of competences that 'include knowledge, skills, attitudes and values that allow a person to act in coherent and responsible ways that change the future for the better' (OECD, 2019b, p. 2). Despite actually having been around for at least the last three decades in various iterations of core, generic, key, transferable or 21st century skills, (Tight, 2021), little progress has been made in figuring out how these are to feature in curriculum frameworks.

The OECD pulls in two directions, asserting a commitment to subject disciplinary knowledge – 'meaningful sequential structure of topics that reflect the logic of the academic discipline/disciplines on which they draw' (OECD, 2020a, p. 26) – but also to generic skills, focusing on skills to prepare for a changing workplace, but also skills that are intended to foster social cohesion and an ecological orientation to the world. The framework thus appears to want it both or all ways, pointing compass-like in all directions but with no clear true north. The metaphor of the compass itself is telling, aiming to 'emphasize the need for students to learn to navigate by themselves through unfamiliar contexts, and find their direction in a meaningful and responsible way, instead of simply receiving fixed instructions or directions from their teachers' (OECD, 2019b, p. 2). This spells out clearly the ideal learner as an autonomous life course entrepreneur. The neoliberal overtones are hard to ignore.

The social logic of curriculum models: competence and performance

The name 'traditional' is misleading in several senses. When related to curriculum, the term takes its first meaning, at least in Europe where schooling first began to massify, in the sixteenth century with Peter Ramus in Paris who was the first to codify a curriculum. Up until then, instruction was an oral art, and each teacher decided what to do as he (invariably he) proceeded. There were no set subjects or topics, and pedagogical authority vested in the oral presentation of the teacher, deriving in the last instance from Aristotle, hence also known as 'classical'. Ramus did not only produce the first written curriculum, but he also ordered the curriculum topics, both horizontally – designing topic clusters into proto-disciplines he called 'arts'; and hierarchically, from particulars to universals. In this way was born the modern 'traditional' curriculum with its ordering into subjects which were internally structured by curriculum sequencing and progression principles (Ong, 1961; Hamilton, 1990; Triche and McKnight, 2004). This new pedagogical object could also for the first time be printed by Gutenberg's printing press, and the result went through 150 editions in 45 years. For the first time the curriculum could be disseminated for consideration at a distance, and knowledge progression could be topographically displayed. This allowed the widely distributed expertise of European scholars to be harnessed and focused on refining an increasingly common project. This new pedagogical procedure came to be associated not with anything progressive but with method and seen as a tool for producing stultifying conformity.

German romanticism formed the philosophical basis for a revolt against this radical externalization of knowledge, and the basis for proto-progressivist alternatives to what was by now the mainstream in schooling. These provided the basis for nineteenth century alternatives such as Froebel, Hebart, Pestalozzi, Steiner and Montessori. Even Dewey's system derived from Hegel. The main point about these alternative systems was that, with the partial exception of Dewey, they all remained peripheral to the mainstream traditional curriculum. What they all had in common was a greater or lesser reaction to traditionalism's rationalism, an emphasis on the inner life of the learner, and the desire to release the inner nature of the learner through minimal direction and imposition.

Even at the time, not everyone welcomed the romantic promise. Antonio Gramsci said of the progressive Gentile reforms in 1929, 'The new education created a kind of church that paralyzed pedagogical research. It produced curious aberrations like "spontaneity," which supposed that the child's brain is like a ball of string that the teacher should help unwind. In reality, each generation educates and forms each new generation. Education opposes the elemental biological instincts of nature' (quoted at <http://www.nationalreview.com/article/445038/educational-reformer-hirsch-promotes-knowledge-against-its-enemies>).

These are, in brief, the antecedents to 'traditionalism' and 'progressivism'. But that tells us very little about the particular purchase progressivism has exercised on mainstream educational thinking since the 1960s, when progressivism seemed to experience a second life. Why and how did progressivism emerge from the alternative shadows and make a bid for the mainstream in the late 1960s? Bernstein (2000) traces this to a marked convergence in the social and psychological sciences around the concept of 'competence'. A 'competence' is an inner or in-built potential for some or other specialized repertoire. It is something that must be activated and actualized, not something that is acquired from outside. Bernstein goes on to anatomize the 'social logic' of the concept of 'competence':

1. One has a 'competence' – say, a competence for math – by definition, just as one has for one's mother tongue. If one is not competent, it is not something that one lacks. Rather, the 'competence' has not as yet been activated. Hence, as Bernstein (2000, p. 43) says, given time and the right conditions, 'competence' prefigures a 'universal democracy of acquisition'.
2. The learner is active and creative. External imposition of instructional content can hinder rather than enlighten the learner.
3. This means in turn that the learner self-regulates; learning should be emancipatory, not regulatory.
4. This leads naturally to a suspicion of pedagogical hierarchy, that between learners and between the learners and the teacher. The best teacher is thus a facilitator and midwife to the emergence of competence.
5. The focus is on the present, not the past (the canonical curriculum and its content) nor on an anticipated future where the reality of work and its specialized cognitive requirements lies in wait; the active emancipatory present is the target.

'Competence' is thus the emblem for the rejection of the externalized knowledge necessary for a common curriculum; 'acquisition', like 'transmission', points to educational activities of the outside and thus transgresses against the creative inner, the ideal wellspring of knowledge in the progressive classroom (see also Wahlström, 2016). Bernstein traces the new mainstream allure of this idea in education to various social movements of the 1960s – the rise of militant student protests, rock 'n roll, the emergence of the 'youth' as a sociological and political subject, and anti-authoritarianisms of various kinds. We might add, the emergence of popular democracy movements. It is small wonder that a younger cohort of educators and teachers would be drawn to the promise of emancipation, democracy and equality that progressivism embodied. In practice, many progressive schools do not have quite the disdain for specialized knowledge that this depiction might suggest, and some have a tradition of producing high levels of performance outcomes. This has not been the case for schools in developing countries, as we have discussed above.

Above all, 'competence' presaged a genuine rupture with the staid and traditional model of schooling that had reproduced inequality so remorselessly, because of a special property. Competence did not so much embrace a route out of power relations; instead, it sought to circumvent them. As Bernstein put it, 'competences are beyond the reach and restraints of power relations and their differential unequal positionings' (Bernstein, 2000, p. 147). No wonder it was, and is, seen as radical. It is a self-legitimizing notion, a 'means of bestowing ideological purity' (Bernstein, 2000, p. 148). To put it simply, the competence-progressive promise was to transcend the cruel strictures of class-determined educational destiny.

If the competence model locates its principle of dynamism as internal to the learner, the principle of dynamism of the alternative model, which Bernstein calls a performance model, is located externally, either in the intended curriculum and its design or in the market. A performance-based curriculum is driven by the amount of content to be covered or tasks to be mastered, by the pace at which they are to be covered, and by the sequence in which they are set. What is evaluated in the competence model is the competence, or potential, of the learner as activated; in the performance model, it is the learner's performance on, or mastery of, the content or tasks prescribed by the intended curriculum.

Two sub-forms of the performance model are relevant for present purposes. They are, first, a specialized sub-form developed during the slow growth of elite into mass schooling. This sub-form is sometimes aligned with elite schooling as a basis for its rejection. Undoubtedly, performances form a hierarchical rank which delivers 'winners' and 'losers' (Sandel, 2020). We will refer to this sub-form as the 'autonomous performance form'. The second is a sub-form we shall call the 'generic performance form', where the external dynamism comes not so much from the knowledge base itself as from the presumed requirements of the marketplace, either the one currently in place, increasingly the ones presumed to be in force in some or other future. The content to be mastered is embodied in, and indexed by, generic skills such as 'working in a team', 'communication skills', sometimes referred to collectively as 'core', 'key' 'critical', 'transversal' (EU 2007) or '21st century skills' (Trilling and Fadel, 2009; McPhail and Rata, 2018). Qualifications frameworks and outcomes-based curriculum systems are systems that stipulate the curriculum in such generic skills-based terms, which if left unqualified, lead to an under-specified curriculum.

The generic performance sub-form is a confusing one because, as Bernstein says, it shares fundamental features in common with the competence model, in that it stipulates general attributes which all learners should, and the implication is could, attain. It shares some of the democratic aura of competence, and is consequently at times seen as progressive, as a component part of a competence model. Wahlström (2016), in an analysis of the impact of recent EU prescripts of 'transversal skills' on the Swedish school curriculum, using Bernstein's competence and performance template, sees it in these terms.

Our argument is rather that future oriented generic skills are external to learners, not part of their internal creative spark. As Allais (2014) points out, the rationale for all generic skills is to be of instrumental service to the present or future market, whether that 'market' is couched in labor market terms or, as is increasingly the case, in terms of the future life course of the individual learner. This makes generic skills integral to a neoliberal rather than a progressive emancipatory social project which would regard any attempt to bend the inner creative potential of learners to instrumental ends as a deformation of creativity. We view the generic performance sub-form as a close fit with '21st century skills', albeit often couched in competence-style rhetoric.

What this means in terms of Bernstein's conceptualization is that the 'third wave' of transnational curriculum policy marks a shift in tension, from that between competence and performance, to one between sub-forms of the performance model. While this might superficially seem to be a less pernicious tension, it masks a central feature of the generic sub-form, namely, that it is inimical not only to disciplinarily based knowledges but is more particularly inimical to specifying curriculum content in anything other than learning outcome terms. We will illustrate this by means of a brief excursus into South African curriculum history, only because South Africa encountered a radical form of a generic curriculum early on, in the 1990s. The point of the argument then is to illustrate what this 'third wave' generic performance form might mean for developing country learners if it becomes the next export to these countries.

South Africa's curriculum 2005: a cautionary tale

South Africa launched its first post-apartheid curriculum with a radical skills agenda, comprising an outcomes-based framework coupled with a commitment to learner-centred and constructivist pedagogy in the classroom. This national curriculum, Curriculum 2005, started first in the junior grades, but was to be progressively rolled out to all grades by 2005, hence the name (Department of Education, 1997). At its heart was something called radical outcomes-based education. Although couched in discourses of transformation and democracy, the intended national curriculum was an extreme version of an outcomes-stipulated curriculum, a radical generic performance curriculum somewhat ahead of the global vogue spelt out above.

Like all outcomes-based systems, it looked upon traditional school subject boundaries as impediments to be transcended, so in their place were eight transdisciplinary learning areas, to be translated into learning programmes by means of a set of design features, none of which stipulated the content to be learnt: there were twelve critical outcomes, which would now be called '21st century skills'; 66 specific outcomes which despite the name were generic across grades; 237 assessment criteria; range statements specifying level and depth (but not content); performance indicators; and Expected Levels of Performance. Teachers, in addition to supplying all their own content, were expected to report on all these indicators for every class (Hoadley, 2018).

Problems arose almost from the start, which the designers responded to by adding generic design features, 'stipulating finer and finer levels of outcomes' (DOE, 2000, p. 30) in line with Knight's remark above. When that did not help, the Minister of Education commissioned a review. Despite phrasing the result in diplomatic terms, the verdict was damning, finding the curriculum 'technically over-designed, yet remains under-specified' (DOE 2000, p. 41). The Review further found incoherence amongst the design features, with no conceptual sequence and progression path stipulated. This was particularly disabling for knowledge domains dependent on selection and sequencing, like Mathematics. This left under-prepared teachers and learners without a curricular road map (Jansen, 1998).

The resultant chaos was gradually revised in three iterations. This entailed a gradual shift to a knowledge-based, or autonomous performance curriculum model, leading to the Curriculum and Assessment Policy Statement, or CAPS (DBE, 2011). CAPS entailed detailed content specification and strong controls over the sequence and pace of curriculum coverage, viewed in some quarters as a neoconservative shift back toward the traditional curriculum to which it bore some structural similarities (Shalem, 2018). Under the CAPS there has been gradual improvement in student achievement outcomes, although off a low base.

At the end of 2020, pressure from the global generic skills movement is again felt in the Department of Basic Education with calls to re-integrate '21st century skills' into the curriculum. The thrust this time is a neoliberal one, unlike the progressive intentions and pedagogy of Curriculum 2005, focused predominantly on the changing nature of work now and in the future. In addition, and particularly under the conditions of the COVID-19 pandemic in 2020, a discourse of 'self-directed learning' would appear to stress again the virtues of the 'autonomous learner' and personal responsibility for success, or as the case so often is in developing contexts, failure.

Conclusion

This chapter has looked at the age-old tension between traditional and progressive curriculum models, between what Bernstein has called performance and competence curricular forms, and has discussed how a progressive learner-centered form of the competency was exported to less-developed countries. We have argued that while this tension can be said to have framed curriculum debates in the past, a new tension has more recently come to the fore. This is the tension between the autonomous and generic sub-forms of the performance model. The generic sub-form has adopted aspects of the competence model, at least rhetorically – the preference for an integrated rather than a subject-based curriculum, and a focus on the self-directed individual. But the differences are more significant; the competence model might prefer not to over-prescribe content, but outcomes-specification design blocks it. Where the first takes a moral position against content, allowing it to creep in by the back door, the latter's design precludes it. Finer and finer levels

of outcome specification do not mitigate this design problem. Both forms take the individual as their principal actor, but where the competence individual progressively releases and specializes their inner creativity and innovativeness, the generic individual accumulates outcomes in Sysiphean fashion (Muller, 1998), each of which has a limited specialization span. The former curriculum faces toward a world of individual innovation, the latter toward the market.

The final question is why generic curricula have proved so attractive. The proponents will say that the generic curriculum is the only way to prepare learners for a world of change, now but especially in the future as the rate of change speeds up. A more mundane but nonetheless pressing reason might be that it becomes progressively harder to make sensible selection of content, to cater for both breadth and depth. This may be because specialization has advanced to such an extent that new knowledge keeps crowding into the curriculum, or it may be because of the proliferation of new fields, like media and data literacy, bidding for inclusion in a curricula vehicle that has limited possibilities to expand. Either way, curriculum overload has become a serious problem globally (OECD, 2020b). It is no longer enough to say that the curriculum should concentrate on 'big ideas'. It may seem that the solution is, by means of outcomes-stipulation, to sidestep the problem of content proliferation altogether.

As we have argued, however, outcomes-stipulation comes with consequences that makes life difficult for teachers everywhere, but especially in classrooms in less-developed countries, where poorly prepared teachers rely on an explicit roadmap of the kind that the generic performance curriculum model is unable to provide. If this kind of model is exported to less-developed countries, then their chances of narrowing the performance gap with the more-developed countries will be vanishingly small.

Introduction

Since the late 1990s, important reforms aimed at transforming curricula in compulsory education have been implemented in many industrialized countries. Such developments have taken place in a context where comparisons of education systems and students' competences have taken center stage through the work of the Organization for Economic Co-operation and Development (OECD). Thus, in the 1990s the OECD has defined key competences, that are independent from national curricula:

In its PISA and DeSeCo projects, the OECD promotes a view that what matters is not what is learned about the world, but what competencies and orientations (such as motivation to be a "life-long learner") are being produced in learners, as if these are essentially culture-neutral and context-free. The assessment programs themselves are not tied to what schools have taught in particular countries, but to what problem-solving abilities and "competencies" are agreed to be the desired outcomes of mathematics or literacy or science.

Yates and Grumet (2011, pp. 5–6).

This has increased concerns about the requirements of the "knowledge society," shifting the attention of policy makers to the curriculum (Robertson, 2005; Yates and Young, 2010). Contemporary curriculum reforms share important common features. A perceived change in the skills, knowledge and dispositions needed for success in modern societies and a globalized economy has contributed to a shift toward the use of "competency or skills-based curriculum" (Whitty, 2010). According to Young (2011), assumptions of the knowledge society has led governments to focus on four priorities: (i) a "generic" approach which plays down specific knowledge contents in favor of general and "content-free" competences and skills, (ii) individual learner choice rather than curriculum prescription playing a major role in how the sequencing of learning is structured, (iii) the increasing importance of informal or "non-school" learning and experience, and (iv) the shift from syllabus to learning outcomes. In contrast, "traditional" curricula centered on subject-specific contents are being dismissed as less valuable in the knowledge economy (Mangez, 2008; Robertson, 2005).

As a result, some scholars argue that we can observe the diffusion of a "global curriculum" (Meyer, 2007). Looking at worldwide patterns in compulsory education curricula, it can indeed be argued that much of the formal content of these curricula have become standardized. According to world culture theory, educational systems have converged toward the same "world standards" with regard to the structure, organization, and content of education. Meyer and colleagues (Kamens et al., 1996; Meyer et al., 1992) have shown that even curricula within highly dissimilar countries have converged in the last few decades, especially at primary and lower secondary education. More recently, the analysis of curriculum guidelines from about a hundred countries collected by UNESCO points to a shift from content-oriented to learning-oriented curricula, while individuals are seen as self-regulated in their approach to knowledge (Rosenmund, 2007).

World culture theorists argue that a single global model of schooling has spread around the world, however the idea that globalization has led to policy convergence is one that continues to be much debated among education policy researchers.

More recent analysis invites us to use the world "global" cautiously. Based on a literature review of available research on competence-based education reforms, Anderson-Levitt and Gardinier (2021) found that such reforms seem to have strongly influenced European countries, peaking in the early 2000s. They have been embraced by some African countries, and have affected some Australian states and some Canadian provinces, but only touched the United States lightly, and only anecdotally affected Latin America and Asia.

Secondly, whereas world culture theorists have identified common patterns, researchers looking closely at specific countries or regions tend to find that curricular transformations are more complex and less unidirectional. In certain cases, curricular policies have moved “back” to older forms, for example the standards movement in the US that work at “countercurrent to reforms in which students drive the curriculum” (Anderson-Levitt, 2003, p. 12). Other countries have implemented competency-based reforms but later stepped back from some or all of the reform, such as Sweden, England, Japan, Poland and the Flemish community of Belgium, shifting back toward more discipline-focused curricula in a pendulum swing movement (Anderson-Levitt and Gardinier, 2021).

In some national contexts, contrasting policy responses to globalization have been identified, illustrating the tensions arising between the desire to experiment new forms of learning and teaching, and the pressure to perform on standardized tests (Lingard and McGregor, 2014). Some scholars highlight the tension between the logic underlying contemporary curricular policies, for example between the rise of so-called constructivist models, the call for active learning and creativity and, more recently, a focus on fundamental and “basic” knowledge (notably language and mathematics) and performance measured by standardized assessments (Lingard and McGregor, 2014; Rochex et al., 2011). These performative pressures are linked to the implementation of accountability policies and “post-bureaucratic” modes of regulation (Maroy, 2009), i.e. involving control based on results and no longer on compliance with the law and rules. As highlighted by Anderson-Levitt and Gardinier (2021), much more investigation is needed to establish the link between competency-based approaches to New Public Management and standardized assessments.

Finally, while a certain convergence seems to be effective in terms of national policy statements (Rosenmund, 2007; Voogt and Roblin, 2012), other research focusing on national case studies shows that curricular models do not spread identically, in particular because of translation phenomena (Anderson-Levitt, 2003) favored by the semantic vagueness of the concepts at the heart of these reforms, such as the notion of competence (Ropé and Tanguy, 1994). This polysemous notion has led to hybrid forms of discourse and policy implementation. Recent empirical work in comparative education has therefore focused on the ways in which policies change as they travel across different political, social, and geographic contexts, and how they are variously and uniquely taken up in national policy settings, using a variety of concepts from indigenization, vernacularization, recontextualization, or creolization:

Empirical research in the global education policy field suggests that national institutions and domestic politics are key to understanding, on the one hand, the uneven level of diffusion and penetration of global education policy ideas in different territories, and, on the other, the re-contextualization and (on occasion) the drastic transformation of such global ideas within local institutions, networks of rules, and local practices.

Mundy et al. (2016, p. 9).

Despite renewed interest in “curricular” issues (Lingard, 2010; Priestley and Biesta, 2013) the analysis of these complex dynamics is still underdeveloped, as curricular issues (knowledge, pedagogy, in other words, the internal aspects of “schooling”) have long been neglected by comparative education in favor of structures and organization of systems (Kazamias, 2009). Few empirical, in-depth comparative research have been carried out on contemporary curricular policies, while macro-level, cross-national comparisons only allow to identify broad, common trends. Large-scale comparative analyses are often based on international documentation and look at the curriculum from their most external and superficial dimension (Forquin, 2008). Nor do these studies make it possible to take account of the temporal depth of curricula and the changes that have taken place in them. Finally, the peer-reviewed academic literature is relatively slim compared to a much more extensive gray literature on the topic (Anderson-Levitt and Gardinier, 2021).

The findings presented in this chapter aimed to contribute to this growing but under-developed field through a synchronic and diachronic comparison of curricular transformations in two francophone education system: France and Quebec.

In many francophone education systems, the “curricular reconfigurations” in progress since the end of the 1990s are underpinned by a “competence-based approach” (Hasni and Lebeaume, 2010; Legendre, 2008). France and Quebec provide two examples of such competence-based reforms. In these two education systems, the study programs for compulsory schooling underwent a major overhaul in the mid-2000s. These curricular transformations have given rise to heated controversies, both professional and scientific. Within the scientific community, interpretations of the nature and meaning of these transformations differ widely, from the profound restructuring of learning through the advent of a new “paradigm,” to the instrumentation of teaching contents to satisfy the needs of the “knowledge economy.” These interpretations are not always based on empirical research, and above all, they are based on oppositions that create artificial dichotomies that limit our understanding of contemporary educational policies and their implications. Using Alexander’s terms, the debates revolve around an “oppositional discourse polarized around dichotomous pedagogies” (2006, p. 733)—e.g. progressive vs. traditional, child-centered vs. subject centered.

The rest of the chapter is divided into three sections. First, we present the main conceptual framework that informed the study. The sociology of the curriculum, and particularly the concepts developed by Bernstein (1975, 1990) provide heuristic tools to analyze curricular changes comparatively. The following and central section focuses on the comparison of the two policies and shows how common orientations are recontextualized according to logics and dynamics specific to each educational system, resulting in both countries in hybrid forms or “mode mixing” (Muller, 1998) combining elements of contrasting pedagogic models. Finally, the conclusion returns to the partial convergences and variations observed between the two cases, highlights the ever-changing dynamics underlying contemporary curricular policies and what it means for the further development of comparative curriculum research.

Bernstein's pedagogic models: a heuristic framework to compare curricular transformations

The analysis that led to the findings presented in this chapter drew extensively on the conceptual framework Bernstein developed in his latest work in relation to educational change in the 1980s and 1990s. His concepts provide important tools for understanding the complex “dynamics” of educational change (Sadovnik, 2006) and accounting for the hybrid forms that contemporary curricula can take, mixing different models to respond to conflicting demands (Muller, 1998).

The “language of description” he developed aimed precisely at facilitating empirical research in a variety of contexts, allowing researchers to map empirically curricular changes across three key dimensions, which he referred to as “message systems”:

Formal educational knowledge can be considered to be realized through three message systems: curriculum, pedagogy and evaluation. Curriculum defines what counts as valid knowledge, pedagogy defines what counts as a valid transmission of knowledge, and evaluation defines what counts as a valid realization of this knowledge on the part of the taught.

Bernstein (1971, p. 41).

This ability to embrace curriculum, pedagogy and assessment all at once contributes to the strength of this conceptualization (Broadfoot and Pollard, 2006). In particular, the concepts of classification, framing and evaluation provided a common language to characterize curricular transformations in both education systems. These are three constitutive dimensions for the study of pedagogic discourses and practices.

Classification refers to the organization of knowledge or how different contents co-exists within the curriculum. A strong classification refers to a highly differentiated curriculum, a high degree of separation between categories (between disciplines, and within a discipline, between different contents); a weak classification refers to an integrated curriculum in which boundaries are blurred, permeable, with less specialized discourses. A strong classification can also mean that the boundaries between school and everyday knowledge are made visible. There is a strong classification between inside and outside the institution, and a hierarchy of knowledge exists between “common sense” knowledge and school knowledge. This is referred to as “collection” type curricula as opposed to the “integrated” type in which contents are subordinated to an overall conception and become part of a whole (Bernstein, 1971).

Framing refers to the transmission of knowledge and the distribution of control over pedagogic communication or “who controls what.” Strong framing is where the transmitter has explicit control over the communication; weak framing gives the learner more apparent control over the communication. Framing refers, on the one hand, to the control that is exercised over the selection of pedagogic communication, its sequencing (what comes first, what comes next) and pacing (or rate of expected acquisition). On the other hand, framing refers to the “regulatory discourse” which governs the forms that hierarchical relations take in the pedagogic relationship and expectations in terms of conduct, character, manner. These will vary according to a more or less strong framing—learners are expected to be conscientious, attentive, careful, hard-working, and at the opposite pole, to be creative, interactive, and to make his or her own mark.

Evaluation is the third key dimension of the pedagogic relationship. Evaluation criteria may be explicit or implicit. When the criteria for producing the expected text are explicit, the assessments are such that the learner knows on what he or she is being assessed in a particular assessment. It is not so much a question of producing an original and personal text as of reproducing specialized knowledge. Conversely, when the assessment is such that only the teacher knows what he or she is trying to assess, the criteria are implicit or diffuse.

These concepts are central to understanding the specificity of what Bernstein calls the pedagogic discourse, that is, the specialized form of communication encompassing curriculum, pedagogy and evaluation: what is taught to whom, when, where, how it is transmitted and how it is evaluated or deemed as acquired (Bernstein, 1990).

On the basis of these three dimensions, Bernstein (1975) identified two generic types of pedagogic discourse and practice. To describe them briefly, the visible model is characterized by a strong classification of contents, a strong framing of pedagogic relations, and explicit evaluation criteria. Visible pedagogy always places the emphasis on the learner's performance, and the extent to which it is meeting the expected criteria. An “objective” grid exists to assess learners, a grading system allows to compare learners and schools. In terms of sequencing, the rules are explicit and mark very clearly stages (what should be acquired when, in which order). This pedagogy is often based on behaviorist approaches to learning. In the case of an invisible pedagogy, classifications weaken and tend toward an integrated type of school knowledge code. Sequencing is loose, implicit, and only the teacher knows the specific objectives he or she is pursuing, objectives that are underpinned by a theory of the child's development. Invisible pedagogy is less concerned with ranking learners and comparing productions, because differences between learners' achievements reveal the uniqueness of each individual—thus they cannot be used to compare and stratify learners. Their focus is not upon a “gradable” performance but upon procedures internal to the acquirer (cognitive, linguistic, affective, motivational).

Bernstein (1990) later enriched his concepts (and the main, dichotomous opposition visible/invisible) in particular to capture the contemporary curricular reforms taking place in the UK. He further distinguished between two modalities of visible pedagogy. One is called “autonomous,” the other “dependent,” primarily oriented toward external demands (especially relevance to the labor market):

Here the opposition is between a pedagogic practice dependent upon the market place for its orientation and legitimation [...] and a pedagogic practice independent of the market place, claiming for itself an orientation and legitimation derived from the assumed autonomy of knowledge (1990, p. 63).

Table 1 Invisible pedagogy and visible pedagogy (autonomous and dependent modalities).

<i>Dimensions of pedagogic discourse</i>	<i>Invisible pedagogy</i>	<i>Visible pedagogy—dependent (or market oriented)</i>	<i>Visible pedagogy—autonomous</i>
Classification	Weak boundaries between disciplinary subjects and between school and non-school knowledge.		Strong—usually discipline-based curricular structures.
Framing	Weak Learner conceived as self-regulating, creative and active in the construction of knowledge and meaning. Personalized or individualized control over learners.	Strong Learners have relatively little control over selection, sequence and pace. Hierarchies in teaching-learning relationships are more explicit.	
Evaluation	Evaluation criteria and rules for producing the legitimate texts are implicit and diffuse. A theory of child development underlies the evaluation made by the teacher (interpreting the manifestations of inner competence).	Evaluation criteria and rules for achieving a legitimate text are relatively explicit. Emphasis is on a specific output expected from the learner. Learners' texts (performances) are objectified by grades and stratified.	

Adapted from Bernstein (1990).

The “autonomous” visible pedagogy (which, from a diachronic point of view, precedes the dependent model) aims to construct autonomous subjects, emancipated from their family and local belonging, thanks to a teaching body largely independent from the political power and local communities. It promotes a school culture that preserves a high degree of autonomy from economic and social pressures, emphasizing knowledge as a factor of intellectual enrichment: “The autonomous visible pedagogy justifies itself by the intrinsic worthwhileness and value of the knowledge it relays and by the discipline its acquisition requires” (Bernstein, 1990, p. 87).

The second form of visible pedagogy has developed in a context centered on the efficiency of education and relevance to market demands. Since the late 1980s, the fundamental transformation in the field of educational policy lies in the institutionalization of models that value above all performance and the objective of integrating individuals into the market, in a context where work and life can no longer be based on stable predictions of the future. In that sense, it is externally regulated. This pedagogic model is characterized by instrumentalism (focusing on school rankings, skills as an investment to increase future educational and professional opportunities). The learning acquired at school becomes resources for inter-individual competition, linked to the imperative of employability (van Zanten, 2009). According to Bernstein, this dependent, instrumental model incorporates some of the criticisms that could have been expressed with regard to the autonomous model: elitism, knowledge that refers only to itself, indifference to the consequences in terms of stratification, obsolete curricula that do not arouse the interest of children from working-class backgrounds. This dependent model thus tends to translate into “mixed” pedagogic regimes drawing on features of invisible pedagogy: for example, greater permeability between school and life. In this sense, this new pedagogic discourse incorporates features of apparently oppositional discourses (Table 1).

Curriculum policies in France and Quebec: a comparison

Competence-based curricular reforms in two contrasting education systems

The two reforms under study resulted from large-scale national debates which insisted on the need to adapt the curricula to the needs of the 21st century but also to ensure the success of all pupils and address the problem of early school leaving (Box 1).

If the French and Quebec education systems share common characteristics, these are also two contrasting systems in terms of organization, weight of the different institutions, school culture, values and curricular traditions. The French education system is characterized by a degree of administrative centralization that remains strong, while in Quebec regional education bodies have a relatively high degree of autonomy. Values of universalism (Holmes and McLean, 1989) remain central to the French system, while at the core of the Quebec system is the project of building a specific education project for Quebec in an Anglophone Canadian context (Rocher, 2004). North American influences such as pragmatism have also been present in Quebec since the 1960s (Lenoir, 2005). Indeed, since the Quiet Revolution, Quebec has distanced itself from the French-style education model (typical of the classical colleges, where the elites of French Canada had been educated until then) in the name of democratizing education. The “Parent Report” (1963–1965), which led to the most important educational reform in Quebec, included a strong criticism of the obsolete and elitist model of the classical colleges, with its bookish pedagogy and emphasis on scholarship. The “renewed” humanism, drawing on humanistic psychology and pragmatism, valued so-called active pedagogy, the taking into account of children’s particularities, and the recognition of the pluralistic character of society (Lenoir, 2005).

Box 1 Research methodology

This chapter draws on a doctoral research project carried out between 2012 and 2017 which aimed at analyzing contemporary curricular transformations in lower secondary education in France and Quebec (Canada).

The multi-level comparative research focused on compulsory education, excluding vocational education and higher education which have their own distinct history of competency-based reforms. The *collège* in France and first cycle of secondary school in Quebec correspond to the last years of compulsory education, where all pupils follow a common pathway (before moving into different tracks, e.g. general upper secondary education or vocational education and training for instance).

The study aimed to compare how similar “competence-based reforms” in lower secondary education—partly drawing on the same ideas, pedagogic models and experts—were recontextualized at the “national” and meso level. In Canada, education comes under provincial jurisdiction. Each province has the power to establish its own education system and to make all decisions regarding schools, teachers and curriculum. We therefore considered Québec’s education system as a unit of analysis comparable to the French one. The second strand of the research (which is not presented in this chapter) examined the practices of pedagogic advisors (Quebec) and inspectors (France) based on fieldwork carried out in three mid-level education authorities.

The research focused on what the Ministry legitimizes as “official pedagogic discourse,” constituted by the legal and regulatory texts governing the functioning of schools, official syllabus, teaching guidelines and other support documents. The Quebec corpus comprised 18 texts and the French corpus 24 texts. They were constituted by the following texts:

- Legal and regulatory texts. These include the study programs which constitute the main mediating tools between the level of decision-making and work in schools (Mangez, 2008). We focused on two disciplines, French as a language of instruction and mathematics, because of their weight (hours of teaching) and relative importance in the curricula, but also in the evaluations (local, national, international) of pupils’ achievements.
- Administrative documents (service notes, circulars, ministerial instructions) that specify how legal and regulatory texts are to be implemented.
- Supporting or accompanying documents (various guides and pedagogical tools developed by the ministry and its departments) which do not have a prescriptive value but can nevertheless be central in teachers’ work.

Our approach and empirical material differed entirely from the methodology adopted in large-N comparative analyses. For example, Kamens et al. (1996) used reports on the curricular outlines of secondary education programs worldwide found in compendia produced by international and regional conferences. This is the formal curriculum in its most “external” and “superficially institutional” aspect (Forquin, 2008, p. 104), with data processing being limited to identifying the presence or absence of different disciplines and their respective place. On the contrary, the choice of our data aimed to reveal the plurality of forms that changes take in different national spaces, as well as the hybridization processes between different logics and models that underpin national education policies (Maroy, 2009).

To analyze the corpus, we developed an analytical grid based on the Bernstein’s key concepts which allowed us to construct a common theoretical denominator beyond national contexts. The thematic analysis aimed at characterizing the transformations of the official pedagogic discourse along its key dimensions. The analysis of these data was carried out to reveal diachronic variations (2000–2012) in each system and synchronic variations (between the two education systems). For the full presentation of the methodology, see Mathou (2018).

The Pedagogic Renewal in Quebec

The decision to undertake a reform of Quebec’s education system stemmed largely from the Estates General on Education (EGE) held in 1996. In 1995, the left-wing Parti Québécois (PQ) government established the Commission for the Estates General on Education (EGE) to review the entire education situation in Quebec. The overhaul of the curriculum was intended to allow for the democratization of educational success.

The Ministry of education then began elaborating new study programs for primary and secondary education, based on a new approach to curriculum-making. Until the late 1990s, curriculum development was entrusted to groups of experts in their discipline, with little cooperation between these groups (Carpentier, 2010). Moving away from this compartmentalized approach, more than four hundred teachers, principals, counselors, education professionals and academics actively participated in the design of the new programs (Lessard et al., 2007).

The new Quebec Education Program (QEP) for lower secondary education was published in 2003 (MEQ, 2003) and was gradually introduced from 2005, when the reform was renamed “Pedagogic Renewal.” The QEP is organized around the development of competences (subject-related and cross-curricular competences) which reflect the goals to be attained at the end of compulsory education. Disciplines are grouped into five “learning fields” (languages, mathematics, science and technology, social sciences and the arts and social development) that are supposed to highlight the interdependence of these fields of knowledge. In addition, the QEP puts a very strong emphasis on two key elements. The first is the definition of “general education fields” such as health and well-being, media literacy, environmental awareness and consumer rights. The second is the definition of cross-curricular competences (defined as the intellectual, methodological, personal, social, and communication skills) common to all learning fields. Finally, the QEP is structured around 2-year learning cycles, allowing the progression of each individual pupil at his/her own rhythm.

Following the publication of the QEP the Ministry published its policy on the assessment of learning in the spirit of the Pedagogic Renewal. Assessment was defined as an integral part of the learning process, taking into account a whole range of observations collected in different situations. In line with this vision, the Basic School Regulation (Quebec, 2005) loosely defined the form of the communication to be handed in to parents. The pupils’ results could be expressed in the form of letters using scales of competence levels to reflect pupil’s progress and development. Numerical grades and pupils’ comparisons were strongly criticized.

The orientations defined by the Parti Québécois government were not called into question by the arrival in power of the Liberal Party (PLQ) in 2003. However, from 2007 onwards major changes took shape, in a context characterized by a combination of pressures. The discontent of parents—denouncing incomprehensible jargon and unclear assessment methods—converged with strong teacher union pressure. Around that time, the Liberal Party embarked on a major legislative project, the adoption of the law on results-based management in education, which introduced new rules on accountability and performance evaluation in schools (Maroy et al., 2014).

From 2007 to 2010, the Ministry of Education modified the Basic school regulation several times. The number of report cards were defined on an annual basis, rather than cycles, their content was standardized. Marks obtained for each subject and the group average had to be included in the report card, allowing comparison between pupils within a group. Standardized ministerial assessments were also introduced in one key subject (French) at the end of lower secondary school. Each school was required to set performance targets in advance for pupils' results in these assessments. An addendum to the program, called the "Progression of learning," was published in 2010/2011 specifying the contents to be covered each year, for each subject.

Finally, a "reading intervention" toolkit (MELS, 2011) was published by the Ministry to identify "effective" practices, putting at the forefront practices based on explicit, teacher-centered teaching such as direct instruction. Despite these changes, the central curriculum document, the QEP itself, remained unchanged.

The Common Core in France

In France the curriculum reform followed the national debate on the future of education, chaired by C. Thélot, which formalized the idea of a common core in its final report (Thélot, 2004). The ensuing Guidance and Planning Law of April 23, 2005 called for "every pupil to be guaranteed the means needed to acquire a common core consisting of a set of knowledge and skills that it is indispensable to master in order to successfully complete school education, continue training, build one's personal and professional future and play a successful part in society." Based on the recommendations from a newly created body, the high Council for Education (HCE), the Decree of July 11, 2006 (MEN, 2006) defined the seven broad competences (or "pillars") that all pupils must progressively acquire throughout their compulsory schooling (from 6 to 16).

Subject-specific programs were subsequently revised in order to take into account these competences. However, the groups in charge of the subject-specific program revision worked independently, and more than half of the members belonged to the inspection bodies, contradicting the stated supra-disciplinary logic of the Common Core (Clément, 2013).

The new programs were published in 2008. New assessment tools were also elaborated in line with the "competence-based" approach outlined in the Common Core. The personal competence booklet was meant to be used to progressively "validate" the seven competences of the Common Core throughout compulsory education, allowing teachers to take stock of the pupil's achievements (MEN, 2010).

In the following years, numerous documents with no legal value were published. A first set of circulars defined various "education for" (e.g. health, sustainable development, career choice ...) which would then have to be taken into account in the validation of the competences of the Common Core. A second set of circulars introduced various forms of "individual support" provided to pupils during specific slots dedicated to "differentiated" learning. Between 2005 and 2011, three types of measures were introduced: the personalized programs for educational success or PPRE (2005), educational support (2008), and personalized support (2011).

Following the 2012 presidential elections, the newly elected socialist government passed a new Guidance and Planning Law (July 2013), which announced the review of the Common Core and the creation of a new independent body, the High Council for Programs (CSP). From 2013 to 2015, the CSP drafted a charter to be used as a guide for drafting the new Common Core and new study programs. Working groups corresponding to the three cycles of compulsory schooling were set up, each group being interdisciplinary and including representatives of the various actors working in schools, as well as academics specializing in pupil learning and the areas of knowledge included in the curricula.

Unlike the 2006 Common Core, in which five of the seven competences referred to clearly recognizable disciplinary pillars, the five new "domains" of the 2015 Common Core referred to educational areas or domains and led to a much greater blurring of disciplinary boundaries (MEN, 2015b) (Table 2).

Table 2 The Common Core in 2006 and 2015.

<i>Seven competences or pillars of the Common Core of knowledge and competences (2006)</i>	<i>Five areas of the Common Core of knowledge, competences and culture (2015)</i>
(1) Mastering the French language	Area 1: Languages for thinking and communicating
(2) Speaking a modern foreign language	Area 2: Methods and tools for learning
(3) Basic knowledge in mathematics and scientific and technological culture	Area 3: The formation of the person and the citizen
(4) Mastering common information and communication technologies	Area 4: Natural and technical systems
(5) Humanist culture	Area 5: Representations of the world and human activity
(6) Social and civic skills	
(7) Autonomy and initiative.	

This movement toward greater integration of content was, however, accompanied by a cautious approach toward the risks that may arise from a weak classification of knowledge, a potential source of confusion for pupils. Particular attention was also paid to what was expected of the pupil, the Common Core promoting the explicit teaching of school language, lexicon, understanding of instructions, using school books and note-taking (MEN, 2015a).

Multi-year cycles and “progressivity benchmarks” (indicating the notions to be introduced at the beginning or end of the cycle) replaced annual sequencing. Texts published in 2014–2015 also emphasized less hierarchical relationships and, above all, the recognition of the child’s fulfillment and personality development, taking into account the pupil as an adolescent in the process of physical and psychological evolution (MEN, 2015a).

The recontextualization of common trends into two national contexts

Common trends underpin the curricular transformations observed in the two education systems during the period 2000–2015. The two reform movements originating in the late 1990s/early 2000s, both mark a shift toward the weakening of classifications between types of knowledge and toward the relaxation of the framing of pedagogic relations.

In the two corpus analyzed, we identified a rise in cross-curricular themes that weaken disciplinary boundaries, also the boundaries between the inside and outside of school (Whitty et al., 1994). They are indicators of a strong integration of knowledge. This is accompanied by a shift in the foundation of the legitimacy of knowledge, increasingly based on the relevance with regard to life outside of school, leading to varying degrees of de-differentiation (Young, 2006) between forms of knowledge. These changes are closely linked to changes in teacher-pupil relationships and expectations of pupils, such as the increased personalization of pedagogic relations.

However, there are important variations in the recontextualization of these common orientations, particularly among the logics presiding over the weakening of classifications and framing. In Quebec, this weakening is reflected in a strong permeability between school knowledge and experiential knowledge. Everyday life issues become the stakes of knowledge while subject-specific knowledge becomes a resource among others to deal with these issues. For instance, in the section of the QEP dedicated to mathematics, the theme “Environment and consumption” is tackled through pupils’ daily lives and habits (such as calculating taxes, rebates). The example of “learning situation” provided by the program presents mathematics as a resource among others for dealing with a recycling problem, overshadowing scientific conceptualization (Hasni, 2010).

The permeability between types of knowledge is much less strong in France. While greater legitimacy is granted to the contextualization of school knowledge, everyday, common-sense knowledge is treated with great caution. Cross-cutting themes such as environmental education can give rise to disciplinary crossovers, but each discipline treats the theme in a different way. Thus, the so-called “convergence” themes (MEN, 2008) are somewhat absorbed in the disciplinary code (Whitty et al., 1994): they are distributed across a variety of separate subjects, without significantly impacting the boundaries between these subjects. We can therefore observe two contrasting approaches to the introduction of cross-curricular themes related to “life skills”: in Quebec the subjects are supposed to be taught through the themes, while in France the themes are taught through the subject. Although from 2012 onwards, the official pedagogic discourse grants increased legitimacy to the contextualization of school knowledge, it nevertheless remains cautious about the blurring of boundaries.

Similarly, while the framing of the teacher/pupil relationship is relaxed on both sides, the differentiated approach to teaching is much more institutionalized in Quebec. The affective, personal dimension is at the core of pedagogic relations: teachers must take into account pupils’ fields of interests, learning styles and tastes, as well as their family, personal and social contexts. Differentiation, a leitmotiv of the key texts adopted in the context of the Pedagogic Renewal, is supposed to be the ordinary modality of the pedagogic relationship in the classroom. Teachers are expected to put in place the conditions conducive to “the expression of pupils’ concerns, tastes, feelings, emotions” (MEQ, 2003, p. 23), leading to a form of social control which “involves personality at a deeper level” (Forquin, 2008, p. 33).

By contrast, “differentiation” in the French official discourse is essentially limited to taking into account pupils’ previous knowledge, and remains focused on remediation to bring pupils to the necessary prerequisites (Houssaye, 2012). Measures introducing forms of individualization tend to weaken the framing of teacher-pupil relations, but within well-defined spaces and time frames, and they focus first and foremost in the provision of support to complete homework and revise lessons. These are typical interventions aiming at “giving more education” (Power and Whitty, 2008), thus increasing the frequency and intensity of educational activities without weakening the boundaries between home and school and between teachers and pupils (strong classification and strong framing). The prevailing form of “individualization” in France therefore remains centered on school performance and aimed above all at low achieving pupils.

Secondly, the comparative analysis highlights the complex hybridization of pedagogic models at work in French and Quebec curricular policies. In both cases, the transformations that took place over more one decade entailed the layering of multiple texts resulting in mixed pedagogic models (Muller, 1998). In relation to the three models outlined by Bernstein (1990)—an invisible pedagogy, a visible pedagogy with autonomous and market-oriented modalities—the diachronic analysis shows that these three models and modalities are mixed in varying degrees and according to different arrangements, depending on the period under consideration (Table 3).

In Quebec, the central texts of the Pedagogic Renewal (2000–2007) promoted a highly integrated code of knowledge and an invisible pedagogy. However, toward the end of the decade, the official discourse evolved toward a more hybrid form in which invisible and dependent visible pedagogies coexist. The official discourse has preserved in part the rhetoric of pupils’ personal

Table 3 Main pedagogic orientations underlying the official discourse according to the periods considered.

	2000	2005	2007	2012
Québec	Period 1 2000–2007 Invisible pedagogy strongly asserted through very homogeneous texts		Period 2007–2015 Incremental shift toward dependent, market-oriented visible pedagogy through the layering of new texts to the QEP	
France		Period 2005–2012 Centrality of autonomous visible pedagogy despite the marginal opening toward invisible pedagogic practices		Period 2012–2015 Invisible pedagogy takes center stage in official discourse although adopted in a “cautious” mode

development, but has moved toward a more interindividual competition model, centered on achieving performance measured by standardized tests. Meanwhile, knowledge pertaining to everyday life has retained a central place, and characteristic features of invisible pedagogy have been maintained in sub-segments of the system. Thus, teachers may continue to use competence scales and report cards centered on learning outcomes with pupils with learning difficulties, a common situation according to Bernstein (1990), where the practices that tend most toward invisible pedagogy are reserved for certain sub-groups (disadvantaged socio-economic categories, pupils defined by a “deficit”) or certain “non-verbal” activities (Bernstein, 1975, p. 110). Most notably, the QEP has remained untouched.

In France, the period 2005–2012 was characterized by the marginal shift toward the invisible model. The integration of knowledge was contradicted by the decoupling between the logic of the Common Core and that of subject-specific programs. Moreover, invisible pedagogy was reserved to certain categories of pupils (low achievers), and limited to specific times “outside” the regular classroom. Invisible pedagogy was incorporated in a circumscribed way, within a system where the autonomous visible model predominated. Although the changes adopted in 2012 marked a strong movement toward the invisible model, the official discourse remained cautious with regards to the weakening of boundaries, as a form of protection against the potentially differentiating effects that penalize pupils from disadvantaged backgrounds. This cautious and critical approach to the blurring of boundaries and de-differentiation of knowledge draws on the work of researchers from the ESCOL research group (see e.g. Bautier and Rayou, 2013), some of whom participated in the working groups responsible for developing the programs. Thus, the 2012–2015 discourse can be seen as an attempt to combine “therapeutic” orientations that value the expression and development of the “self,” more permeability between school and non-school knowledge, more inter-disciplinarity, with the preservation of explicit rules of recognition and realization.

Finally, three main interpretative hypotheses can be put forward to account for the variations observed in the recontextualization of common curricular trends. Firstly, historical and cultural factors partly account for the variations in the intensity and modality of the transformations observed influence the degree of legitimacy of invisible pedagogy in each education system. In Quebec, these orientations have been institutionalized for a longer period of time. The reform resulting from the EGE was in part a continuation of the orientations adopted since the 1960s, and initiated by the Parent Report. In France, the recognition of differences (through the individualization of relations with pupils) is still problematic in a system historically built to promote a “universalism” that requires ensuring a uniform distribution of knowledge to all, throughout the country, and through examinations that sanction fair competition (Duru-Bellat and van Zanten, 2012). Thus individualism is valued more than group work, teaching tends to be decontextualized from the daily experience of pupils, the affective dimension is clearly separated from the cognitive dimension (Osborn et al., 2003).

Secondly, factors relating to the processes presiding the production of official texts play a role in the modalities of curricular change. In both cases, the very marked movements toward the weakening of classification have been accompanied by attempts to break with the traditional modes of curriculum production, driven by disciplinary logics (subject-specific professional associations and general inspectorates). New curriculum making arrangements were put in place in Quebec (early 2000s) and France (2012), characterized by the role of a single public body that coordinates the drafting process of all the curriculum components (study programs, teaching guidelines, assessment tools); interdisciplinary working groups organized by cycle (not by year of study) to ensure vertical and horizontal alignment; the involvement of actors at the forefront of the implementation of the curriculum (teachers, pedagogical advisors) but also academic experts specialized in learning processes. Interestingly, our research, although it did not explore this aspect in detail, points toward processes of policy borrowing. For instance, before embarking on the new reform in 2012, the newly created CSP carried out an international comparison exercise to inform its reflection on the new programs and the new common core, based on the experience of a selection of countries including Quebec.

Thirdly, more contingent factors, linked to the strategies of actors and to political and electoral contexts, contributed to processes of juxtaposition and hybridization. Thus, the 2007 turning point in Quebec can be explained by a particular electoral and parliamentary context, combined with pressure from unions and parents. The introduction of results-based management, a major

legislative project in 2008, was thus explicitly linked to the “realignment” of the curriculum (standardized report cards, changes to the programs to prioritize core subjects or “basic” knowledge) in order to increase school performance. As Bernstein and others (see Broadfoot and Pollard, 2006; Halpin et al., 2004; Sadvnik, 2006) have argued, invisible pedagogies are less amenable to public scrutiny and accountability, as their outputs are more difficult to evaluate according to objective and standardized frameworks. In such a model, the differences between learners’ achievements cannot be used as a basis for comparison and stratification, as these differences are supposed to reveal the uniqueness of each individual. Instead, accountability is facilitated by the standardization of the sequencing and pace of learning, aligned with a uniform temporality, and the measurement of performance objectified by numerical assessment. Grades and exams make it possible to construct rankings in order to compare pupils, schools, etc. (Muller, 1998).

In France, the extreme politicization of education policies resulted in the proliferation of texts adopted by successive ministers (Meuret, 2013). The succession of ministers from the right-wing majority in power (F. Fillon, G. De Robien, X. Darcos, L. Chatel) between the adoption of the 2005 Law and the change of government in 2012 produced a mix of heterogeneous texts lacking a clear direction in the changes undertaken. However, unlike in Quebec (where the change in the party in power did not lead to scrapping entirely the Pedagogic Renewal), the change of political majority in 2012 re-launched the whole process of curriculum development leading to a new Common Core and new programs.

Conclusion

The objective of this chapter was to understand how common curricular trends are translated into national curricula. The study presented analyzed contemporary curricular transformations in two national contexts, France and Canada (Quebec), and over a 15 year period.

Our findings illustrate two distinct national declinations of the “global curriculum.” In both contexts, the official pedagogic discourse in the 2000s led to a movement toward the weakening of classification and framing and the invisibilization of evaluation criteria. But far from resulting in a standardization of national curricula, these common orientations were recontextualized according to logics and dynamics specific to each educational system. Long-term historical factors (including curricular traditions), existing institutional arrangements (such as curriculum-making processes), and factors related to the political context constituted powerful filters that maintained strong national specificities in terms of curricular evolutions and policy trajectories.

The analysis also revealed the complexity of contemporary curricular developments, producing composite, mixed pedagogic models, far from clear-cut dichotomies. The composite models correspond neither to what critical perspectives denounce as a device aimed at satisfying market needs nor to what critics of competence-based reforms describe as pedagogism or child-centrism. The analysis thus makes it possible to highlight the complex, ever-changing dynamics underlying contemporary curricular policies.

In France notably, following the presidential elections of 2017, the official pedagogic discourse seems to have taken a new direction, once again. The changes adopted by the new Minister of Education seem to undermine the affirmation of the invisible model. This could be the beginning of a new pendulum swing, shifting back to the autonomous visible pedagogy or toward a mixed regime embedding more instrumental, dependent modalities.

Drawing on the sociology of the curriculum means indeed apprehending the curriculum as the product of an ongoing process of elaboration and institutionalization in which skills and resources are mobilized, interests are confronted, value conflicts and power issues are at stake (Forquin, 2008).

Finally, these results invite us to examine with caution the idea of a necessarily convergent movement between so-called “competency-based” reforms, New Public Management (NPM) and neo-liberal policies. While the rhetoric around “competency-based” seems to converge, there are fundamental differences between the pedagogic discourses and practices in which the notion is recontextualized. An in-depth analysis of the logics that preside over the weakening or strengthening of classifications, framing and evaluation is therefore essential to avoid reducing pedagogic discourse to a relay of ideological messages that are external to it (Bernstein, 1990). This in turn argues in favor more attention dedicated to the curriculum in an era of globalized education policies, and for the further development of comparative curriculum research attentive to on-going recontextualization processes between and within transnational and national policies that influence national school systems (Wahlström et al., 2018).

Introduction

The presentation of polarized debates impoverishes discussions and decision making in education. Simplification is attractive; it prevents us from thinking, debating, and listening. In the field of curriculum this happens with different issues that have been pushed into a scheme of opposites. One of these is centralized curriculum governance vs. teacher autonomy and diversity. In this article we explore this debate and seek to escape its simplification through a key question: Should curriculum governance be centralized to achieve better learning outcomes?

In recent decades we have witnessed the constant emergence of the temptation of curriculum centralization. There are two major parallel histories of this governance shift. The first is the argument that there should be greater curricular centralization in educational systems with lower educational quality. The second is the story of the United States and other Anglo-Saxon countries with a tradition of strong curricular decentralization, where centralization is proposed as a decisive reform path.

One of the most widely read and cited documents on international education policy is the “McKinsey Report” (Mourshed et al., 2010). There, the argument for curriculum centralization in the countries with the lowest educational results is presented at its full potential.

The McKinsey Report invites policymakers around the world to follow a linear and straightforward instructions manual: they should locate their education system in the league table of learning performance and act depending on whether they are among the “poor,” “regular,” “good” or “very good” performing systems. For systems with poor performance, the report, based on international cases of systemic improvement, recommends curricular centralization policies such as scripted teaching materials, coaching on curriculum and instructional time, and provision of textbooks. Instead, for countries with higher results, the report recommends “decentralizing pedagogical rights to schools and teachers” (Mourshed et al., 2010, p. 28).

The McKinsey report has been criticized for its lack of comparative rigor. In generalizing educational policy formulas, it ignores the contexts and the enormous cultural variations of educational systems (Alexander, 2010; Morris, 2015). However, its argument is shared by numerous authors and approaches linked to the need to centralize curricular governance in education systems with a low level of teaching skills.

The argument for curriculum centralization in fragile contexts has also led to top-down solutions. In some cases, it has been proposed that the distribution of free textbooks is a way to establish a practical curricular floor throughout the system. In other cases, it has been proposed to advance more rapidly in curricular centralization through standardized assessments. In the face of low effectiveness of curricular standards, high-stakes standardized assessments can boost incentives to teach what is highlighted by the tests. This is one way of rapid and systemic reform.

Another way of curriculum centralization, which can complement the previous ones, is the development of scripted lessons. An extreme case of this variant is Bridge International Academies (BIA), the world’s largest network of private schools, which operates in several African countries. BIA schools work based on a pre-programmed curriculum delivered to teachers through electronic devices. These contain completely scripted lesson guides that offer word-by-word and action-by-action steps for every lesson teachers are meant to teach. This model, which BIA describes as an “academy-in-a-box,” operates under the assumption that scripted guides are necessary in developing countries where teachers, allegedly and according to BIA, cannot read nor solve primary-level mathematical problems.

In other countries with historically limited state capacities, the private market also influences curricular governance. For example, in Brazil there are “systems of teaching” (*sistemas do ensino*) that are responsible for providing schools with a comprehensive set of assistance: textbooks, teacher training, digital platforms, management systems and professional advice. The schools that hire these systems seek to simplify their task and give more prescriptive lessons and teaching routes to their teachers (Chizzotti and Ponce, 2012).

In these models, curricular centralization seems to be the transitory solution until the capacity of teachers to work with greater autonomy and creativity is achieved. The centralization shift argues that developing countries need a common floor in the face of

fragile contexts. Even in the case of BIA, the curriculum is designed outside the countries, through a private company that seems to follow a logic of efficiency in curriculum governance that the State cannot achieve.

Another version of curriculum centralization comes from the specific context of the United States. Some authors have analyzed the case of the United States as a world exception in its extremely decentralized model of curricular government (Judge et al., 1994). An interpretative approach on this exceptionality says that the US is epitomized by two traditions—"democratic localism" and "individualism"—that oppose state centralization (Timar et al., 1998).

In the 1990s, this diagnosis became a reform laboratory for curricular centralization. Several states began processes of designing a centralized curriculum. The No Child Left Behind (NCLB) Act reform went further, seeking to consolidate curricular foundations for the entire country (Deng, 2010).

In some states the ideas of curricular centralization reached the extreme of tightly regulating teaching work, through the introduction of third-party (mostly for-profit) scripted curriculum programs, understood as ways to homogenize teaching in ways matching "what works," allegedly defined by programs with scientific evidence on their effectiveness (Maheady et al., 2016). Florida offers an example. The Miami-Dade Public School District, one of the largest in the United States, introduced prescribed programs which align perfectly to the requirements of yearly standardized testing. It also issued pacing guides that set the standards needed to be covered during each grade level, with the purpose of ensuring curricular continuity across the district. The state department of education has promoted scripted programs and pacing guides, issuing explicit instructions on how teachers should use the materials they receive, recommending actions such as "verbatim reading" of bold phrases during class.

These two parallel narratives in favor of curriculum centralization converge in many arguments and differ in others. Is the centralization of curriculum governance the appropriate way to improve educational systems? Does centralization improve the equity of the system, providing a common core for all, regardless of the social context? Is it a way to solve the problem of poor teaching quality in developing countries? Is it the way to improve overly decentralized systems?

These questions open the dilemma of curricular centralization. In this article we analyze the historical genesis of this debate in the origins of the educational system. Then we argue that it is necessary to escape the simplification of polarized arguments. Curriculum governance is like a set of Russian dolls or Chinese boxes. What appears to be a simple decision involves other debates. Curricular governance encompasses all spheres of organization and meaning of an educational system. We propose a map to integrate these debates and look for ways to overcome the dilemma.

A historical approach to centralized curriculum

The historical emergence of the concept "curriculum" is associated with the moment of initial development of educational systems in the stage of the Wars of Religion. David Hamilton shows how the concept was born at the intersection between Ramus' educational doctrines and Calvinist religious doctrines in Northern Europe. The term "curriculum" substituted earlier Latin terms such as *ratio* and *disciplina*. The adoption of "curriculum" by Calvinists is closer to the connotations of sequence and linearity and, above all, the Ramist conceptions of order and method (Hamilton, 1990, p. 28).

During the 17th and 18th centuries the first school systems were born close to the religious campaigns. In this context the first models of centralized curriculum emerged. The Ratio Studiorum was the curricular text of the Jesuits, which played a key role in France and other European Catholic countries (Durkheim, 1977). The Ratio was an extremely detailed curriculum, which defined exactly what should be taught at each moment of the school progression. The Ratio allowed different schools to teach the same thing at the same time.

This model of government cannot be dissociated from the organization of the modern school. Together with the Ratio, the Jesuits organized the classrooms with a gradual model of courses organized by age. With the Jesuits individual exercises grew under the control of the teacher, along with grades and exams. The graduated and simultaneous system became an organized machine that allows massive teaching and certification processes.

The pedagogue most recognized for his contribution to the creation of modern educational systems is Jon Amos Comenius. The obsession of the Protestant pastor Comenius was to design a system that could teach "everything to everyone." In his *Didactica Magna*, he raised the idea of a centralized model of government based on the homogeneity, gradualness and sequence of the curriculum. Even Comenius contributed to the creation of what can be considered the first illustrated textbook, the *Orbis Pictus*, which was very popular in 17th century Europe (Comenius, 2019).

As Hamilton indicates, "17th-century theories about schooling contributed to 17th-century theories of political absolutism. The top-down efficiency of the state machine would be assured via the bottom-up inculcation, by means of schooling, social discipline and intellectual deference" (Hamilton, 1989, p. 33).

The origin of the curriculum must be found in this religious-based context of educational systems. The closest concept to the curriculum is that of the Holy Scriptures, the texts that must be reproduced to install beliefs shared by an entire population. It is not by chance that at the birth of schools the Bible was the central learning text, which could be reproduced and distributed on a large scale thanks to the invention of the printing press in the 16th century (Hunter, 1994).

This introductory look at the history of the curriculum shows us the importance of a comprehensive theory. The role of the curriculum cannot be understood without analyzing the functioning of educational systems. In most countries, the consolidation of a centralized curricular governance model was an inherent part of the advancement of state education systems. The French model is perhaps the most recognized in this regard in the 19th century. With a centralizing top-down perspective, the French tradition

installed a homogeneous curricular management model that governed the educational system from the state administration. An example of this systemic power of simultaneous control indicates that in 1896 the French Minister of Public Instruction, taking out his pocket watch, affirmed that at that time, all the 5th-grade students in France were reading the sixth book of *The Aeneid* (taken from Ozouf, 1970).

The roots of educational systems are not homogeneous. In Germany, the concept of *Didaktik* has its own genealogy that allocates a space of autonomy to teachers at the local level. The process of curricular transformation from content (*Inhalte* in German) to teaching (*Gehalte*) was essentially left to the teachers themselves. *Didaktik* is the academic knowledge that includes the specific instructional design as well as the process of performance assessment and creates a space of teaching authority that is distinctive from in the Anglo-Saxon tradition focused on the curriculum (Hopman, 2015).

Theoretical distinctions on curriculum governance

The debate over the centralization of curricular government has many faces. A classic text in the Anglo-Saxon tradition defended the importance of a centralized curriculum. Smith and O'Day (1990) argue for a systemic reform that entails a proactive role by the central units of educational governance (particularly the states), based on the diagnosis that a fragmented policy system with multiple, often incoherent and short-term goals have led to mediocrity in resources and conservatism in instructional practice in the United States. Under the premise that states can overcome this fragmentation through coordinating long-range instructional guidance instruments and that they are in the best position to promote equity, the authors propose the creation of state-led coherent systems of instructional guidance that combine and coordinate three key functions of curriculum governance: curriculum frameworks, pre- and in-service teacher training, and assessment. They suggest this should be accompanied by a revision of the responsibilities attached to each level of governance, and combined with professional discretion by schools, that should be left to decide on staffing, in-service strategies, pedagogies, with support from district and state agencies (Smith and O'Day, 1990).

Faced with the arguments of curricular centralization, Clune (1993) raised a position contrary to that of Smith & O'Day. He argues that a standard curriculum could not address the diversity of needs, that high-stakes testing could lead to the phenomenon of teaching to the test, and that the fragmented, multi-layered governance structure of the United States is not compatible with a system such as that proposed by Smith and O'Day (1990). He claims that it is possible to achieve curricular coherence without centralization, and proposes a system based on decentralized guidance, which he considers more feasible and powerful. According to Clune, instead of defining a standard curriculum, governments should encourage schools to undergo curriculum upgrading processes by joining approved curriculum development networks that provide guidance to generate school-level coherence in terms of content, pedagogies, teacher training and instructional materials. The role of the state and other centralized structures should be that of providing incentives for schools to upgrade their curriculum, developing indicators to track school progress through inspections, and remove obstacles that could come from regulation.

This first presentation of the centralization-decentralization debate of the curricular government is based on its systemic advantages and disadvantages. But this is only one side of the debate. If we open the black box of curricular governance we find another box that takes us to the place that the circulation of knowledge occupies in the educational system. In this sense, Basil Bernstein defines two types of pedagogical discourse: horizontal and vertical. This distinction is essential to open the dilemma of curricular centralization.

The vertical discourse has strong distributive rules regulating access, regulating transmission and evaluation. The vertical discourse is strongly associated with the scientific architecture of knowledge. There are certain closed rules that define what is valid and then distribute it with clear boundaries of organization, rhythm, and validation. The rules are specialized and hierarchical: "vertical discourse consists not of culturally specialized segments, but of specialized symbolic structures of explicit knowledge" (Bernstein, 1999, p. 161).

Instead, "a horizontal discourse entails a set of strategies which are local, segmentally organized, context specific and dependent, for maximizing encounters with persons and habitats" (Bernstein, 1999, p. 160). Horizontal discourse opens the doors of particular views of cultural realities.

The shift from vertical to horizontal curriculum has evident sociological and political consequences. As Bernstein mentions, horizontal discourse could be a crucial resource for "pedagogic populism in the name of empowering or unsilencing voices to combat the elitism and alleged authoritarianism of vertical discourse" (Bernstein, 1999, p. 169). This process marks a shift from equality of vertical reproduction of the curriculum to the recognition of diversity in horizontal discourse.

The debate over the type of organization of knowledge also opens the box of the disciplines. Not everything that is taught in school has the same properties. Within the vertical discourse of academic knowledge production, disciplines belonging to the physical and the social sciences have different knowledge structures. A hierarchical structure is most commonly present in the physical sciences, where general propositions integrate knowledge at lower levels; and a horizontal one is mostly present in social sciences, where a set of specialized languages coexist and have developed segmentally (Bernstein, 2000 cited in Pountney and McPhail, 2017). Some studies have even shown that the structure of the curriculum varies widely by teaching discipline (Schmidt et al., 2001).

This axis of the curricular debate takes on new meanings in the light of recent curricular reforms, promoting a competency-based curriculum aimed at teaching skills for the 21st century (Center for Curriculum Redesign, 2015). Is it possible to integrate the

teaching of skills or competences in contexts of vertical pedagogical discourses? Isn't it necessary to open experiences in the use of knowledge in order to give them local meaning and distribute skills not only anchored in encyclopedic knowledge?

David Perkins indicates that skills require knowledge, but also feelings and motives. Skills are inclinations formed to act in the world, or "big know-how" abilities that connect thinking with understanding and contexts (Perkins, 2014). To teach them is vital to rethink traditional learning organizations and create networks of curriculum design and horizontal questioning.

The organization of the pedagogical discourse opens another black box: the role of teachers in the educational system. In vertical curriculum models, the role of teachers may seem passive. This was exacerbated by traditional centralized views for the organization of educational systems. In the models of curriculum by objectives (Bloom, 1956) there is a taxonomic definition of the path that teaching must take through the world of knowledge: the work of teachers cannot be diverted. This is the tradition of the curriculum as a model to be applied.

The classic Tyler (1969) and Taba (1962) developments present this vision of the systematic, goal-based curriculum. In these models, evaluation plays a central role in keeping the system together and ensuring that objectives are met. According to Taba, the curriculum is, in essence, "a blueprint for learning." This vision of the curriculum as a model has close links with the vertical pedagogical discourse.

In contrast, the horizontal curriculum favors the emergence of diverse and situated educational experiences. This is a conception of the curriculum as a process (Kelly, 2009), which integrates teachers as part of the design of pedagogical paths. Curriculum cannot be isolated from instruction. The pioneering works of Schwab (1959) challenged the passive role of teachers in vertical models of the curriculum. Instead, Schwab proposes to discuss the difficult or "impossible" role of the teacher who must leave the theoretical space to enter the uncertain, problematic, changing, and practical field of real teaching.

Other authors will expand this problematizing vision of the curriculum, where the teacher is a central actor. In 1975 Lawrence Stenhouse defined curriculum as "an attempt to communicate the essential principles and features of an educational proposal in such a form that it is open to critical scrutiny and capable of effective translation into practice" (1975). This definition has a clear correlate in the educational theory of Dewey (1997), who assigned a central place to teachers as creators of unique learning experiences, rather than serial repeaters of content external to them and to the lives of students.

This is how the role of teachers leads us to the next hidden box within the dilemma of curricular centralization: the learning experience of students. The great paradox of curricular centralization is that the greater the verticality of the pedagogical discourse, the greater the scientific rigor is achieved at the cost of losing local significance. Students tend to experience knowledge as something distant and alien. It is a model that favors homogeneous and simultaneous systemic regulation at the expense of the intrinsic motivation of students. In contrast, horizontal pedagogical discourse models tend to take more advantage of contexts and favor individual and group experiences of localized learning (Cox, 2018).

These boxes of the curriculum centralization dilemma show the complexities at stake. Curriculum governance is linked to every aspect of education systems'. It relates to models of curriculum, visions on what is relevant to learn, sociological and cultural implications of the construction and distribution of the pedagogical discourse of knowledge, the role and agency of teachers and the motivation and contexts of students.

Does centralization work?

The boxes opened in the previous section have multiple philosophical, political and pedagogical dimensions. The theoretical conceptions of curricular government are linked to the entire functioning of educational systems. But these questions also have an empirical dimension: does curriculum centralization really work?

The aforementioned McKinsey report (Mourshed et al., 2010), based on PISA data, is a key pillar of the literature in favor of curriculum centralization in developing countries. But there are many other empirical endeavors in this same direction, based on data from international assessments and several other comparative research methods. In the study "Searching for the Golden Model of Education," Bodovski et al. (2017) analyze which characteristics of education systems have influences on the educational results of countries in mathematics. The authors indicate that "a higher level of standardization of educational systems was associated with higher average math achievement" (Bodovski et al., 2017, p. 722). The study found that having a standardized textbook for math was particularly associated with higher average math achievement in a country.

An example of the studies systematized by the authors shows that having mandated curricular guidelines provides a sufficiently balanced curriculum to every student irrespective of the school they attend (English and Steffy, 2001); it also ensures that no inappropriate repetition of the taught material happens as children progress through school (Vulliamy and Webb, 1995). In some countries, changes toward a more centralized curriculum increased the results in international assessments (Walberg et al., 2000).

A more recent study of 19 educational projects across 13 countries in the Global South showed that programs that introduced teacher's guides impacted significantly on learning outcomes, with other factors like teacher professional development and coaching strategies determining the size of these effects. When looking at the intensity of scripting, they found a moderately negative relationship with outcomes: the provision of fully scripted lessons at the beginning and the transition to less structured proposals as the year went on tended to improve outcomes more than word-by-word scripting strategies (Piper et al., 2018b).

As regards textbooks, they certainly affect teaching and learning in several ways. They determine taught contents and ways of teaching (Stern and Roseman, 2004, cited in Behnke, 2018). Studies that have looked at their impact on student achievement show mixed results (Piper et al., 2018a; Polikoff, 2015). Studies conducted in the 1980s and 90s found positive effects but relying

on methods that did not allow to isolate the causal effect of textbooks (Piper et al., 2018a). The most recent ones emphasize the fact that the book itself is not enough to improve performance; but other factors interact with textbook availability to produce. Other authors stress the importance of textbook design when looking at their impact: Glewwe et al. (2009) point out that books may be aiming too high or in a language that children are only starting to learn (Piper et al., 2018a).

Some studies found an effective role of curriculum-based external exit examinations, as systems with this type of high-stakes assessments outperform countries or states without standard exit exams on math and science (Bishop and Woessman, 2004; Carnoy and Loeb, 2002; Fuchs and Woessmann, 2007; Schutz et al., 2007). There are also comparative studies that show the positive impact of centralized examinations on reducing socioeconomic inequalities and tracking (Bol et al., 2014).

However, other studies emphasize that the differences on models of curricular governance cannot be understood without addressing the history and culture of the countries. One of the largest comparative studies of the effects of curricular organization models on student learning, based on data from the TIMSS assessment, indicates this: “variations (on curriculum structures) were consistent with the cultural hypothesis that suggested that curriculum, learning, and their relationship were country specific and that this also likely reflected deeper cultural differences” (Schmidt et al., 2001, p. 282).

A profound study on classroom practices in five countries also found deep culturally embedded differences in curricular governance traditions (Alexander, 2001). A comparative study on classroom practices and educational policies from Cuba, Chile and Brazil found that one of the main differences that explain Cuba’s better performance in international assessments was related to more curricular coherence. Teacher education prepared teachers for the real curriculum in Cuba, while in Brazil and Chile they were far away from classroom realities. However, these differences were related to the profound differences in the state social cohesion of the socialist regime of Cuba and were impossible to separate from this cultural heritage (Carnoy, 2007).

Other studies have discussed the findings of some comparative research that found favorable results in centralized education systems. Westbury and Hsu (1996) discuss the thesis of Stevenson and Baker (1991) on the positive effect that the centralization of the curricular government would have in less variation in the curricular coverage of teachers. The authors point out that countries are not the central variable to explain variations in curricular coverage, but rather the way in which courses are framed. When asked about how curriculum is structured and how are course regulated, the authors find “that the categories of the school and its curriculum reflect and are embedded within larger social understandings defining what schooling or a curriculum mean” (Westbury and Hsu, 1996, p. 136). It is culture and symbolic definitions that are shared within a society at large that explain differences in the governance of curriculum and the enactment process on classrooms and teachers’ practices.

However, it is not only culture that shapes the curriculum voyage to the classrooms. The most sophisticated studies have managed to escape the simplified definitions of curricular centralization vs. decentralization. For example, the classic study “Why schools matter” shows that countries achieve better results when they structure the curriculum with greater focus and rigor: “curricular materials in high-performing nations focus on fewer topics, but also communicate the expectation that those topics will be taught in a deeper, more profound way” (Schmidt et al., 2001, p. 303).

Another study found that the policy tools had little effect on curriculum implementation or on teachers’ perceptions of alignment. “Instead, implementation was related to the availability of multiple curriculum materials in teachers’ schools and to differences between the state’s and teachers’ construal of what standards could be taught with the materials” (Penuel et al., 2009, p. 657). The enactment of the curriculum was much more complex than what centralized policies expected.

Another research drew data from 37 countries that participated in TIMSS to test two different hypotheses related to curriculum governance: location vs. credibility. Schmidt and Prawat (2006) explore whether the location of final authority for curriculum governance (at the national, the state or the local level, for example) matters as a factor for curriculum coherence. The study found that as long as there is credibility around an institutional center with authority over system goals, its location is not relevant when analyzing the overlap in topic coverage between different policy instruments and the consistency among teachers in terms of curriculum coverage.

These studies show that centralization is too much of a broader concept to grasp any significant meaning by itself. Instead, we should look at the many complexities that shape the enactment process of curriculum governance. This is a concrete way of escaping the temptation of the polarization of the dilemma “centralization vs. teacher autonomy.” To move forward this “gray arena,” we conclude this article with some of the key lessons learned on how to rethink the centralization of curriculum governance.

Making sense of centralization

The analysis so far allowed us to open the hidden boxes of the debate on curricular centralization. We have seen that the curriculum cannot be isolated from the rest of the educational system: a systemic perspective is necessary (Schmidt et al., 2001, p. 358). Instead of assuming a fixed position on the dilemma, other authors have proposed a combination. As Deng puts it, “a successful combination model needs to strike a balance between top-down and bottom-up approaches. It needs to acknowledge, on the one hand, the key role of classroom teachers as curricular change agents and, on the other hand, the need for institutional and programmatic curriculum planning in guiding, supporting, and enabling curricular change at the classroom level” (Deng, 2010, p. 388).

Dimensions involved in the design of curriculum policy pile up over each other as overlapping layers of complexity making up a sophisticated enterprise. Unpacking them will provide a way to overcome the centralization/autonomy dichotomy.

A fine-grained look at government action should pay particular attention to the broad spectrum of ways in which curricular messages are (intended to be) delivered to teachers. A way of escaping the simplification of the centralization dilemma is to

shed light on the technical sophistication implied in curriculum governance. Instructional components or instruments for instructional guidance (Cohen and Spillane, 1992) are of several types, each of which operates through relatively stable and predictable mechanisms to influence what and how is taught.

Curriculum frameworks or standards, the documents specifying expectations for what should be taught, express the intended curriculum and usually set the terms of reference for the whole enterprise, which means other components of the instructional complex are based on the directions written in curricular frameworks (Cohen and Spillane, 1992; Remillard and Heck, 2014).

Another relevant instrument for guidance are instructional materials as resources specially designed to support or complement teaching, work as mediators between the intended and implemented curriculum, and thus exert a translational role by offering teachers interpretations of instructional goals through concrete suggestions of instructional activities and classroom sequences (Schmidt et al., 2001).

Teacher training, both pre-and in-service, can work toward guidance as well. Pre-service training can be more or less centrally regulated, through mechanisms as diverse as direct inspection, curriculum frameworks, or certification standards. Its institutional design and other rules surrounding it need to be understood in relation to rules concerning teacher recruitment and licensing policies, which themselves open up a further layer of complexity as regards this instructional component (Cohen and Spillane, 1992). Workshops, courses or programs of different extension and with different kinds of consequences for the teaching career make up in-service training. It shares with initial teacher training its focus in capacity-building, although the extension of training actions in CPD make it a shorter-term strategy with different implications.

Standardized assessments can be curriculum-based, and thus intend to produce evidence on the attained curriculum; or independent of curricula (Eckstein and Noah, 1992). Most importantly, assessments can comprise high or low-stakes for students and teachers. In some systems, exam performance determines student promotion or further education options and thus tend to powerfully orient teaching efforts, even up to the extent of generating unwanted effects such as reducing instruction to the tested curriculum and educational experiences to test item drills. In other cases, exams serve diagnostic purposes and entail no major consequences for school actors, and probably less guidance potential.

These policies have grown over the past 2 decades. Test-based accountability focuses on students' learning outcomes and involves the generation of data through large-scale standardized evaluation instruments. The rise of this new regulatory governance in education is rooted in a new ideology that promotes the modernization and rationalization of education systems through new public management, economic pressures for educational reforms and a global landscape of testing industries (Verger and Parcerisa, 2018).

Another instrument is school inspection or oversight of instruction, which can also steer teaching at the school level. Models vary from more advice-oriented to more punitive ones, and also in terms of the attention paid to curricular content coverage. All of these variables have effects in the extent to and the ways in which inspection can guide instruction.

The curricular environment these instruments make up is crossed by more or less explicit divisions of authority and capacity among a broad range of institutional actors (Elmore and Sykes, 1992). In every setting, around each of the instructional guidance instruments a map of stakeholders can be traced, which adds to the complexity of the matter. The State (at its different levels and through agencies with different degrees of autonomy), the market, subject matter specialists, universities, teacher unions, parents' associations and religious entities all have a stake in curriculum decisions where their spheres of influence are involved. The possible combinations of participating actors, roles they can assume, rules for participation and degree of involvement are hard to fit into the simple centralization/decentralization divide. For example, universities that set admission standards or train teachers affect curriculum; and testing companies are usually interested in supplying assessment instruments that match State-established curricular guidelines (Elmore and Sykes, 1992).

Textbook policies can help depict the sophistication of the matter. The State can either produce the books, regulate their production or use by schools (for example, by setting a list of limited approved options or by making some textbooks compulsory), purchase them from private providers (mediated or not by bidding processes where, for example, curriculum alignment rules can be introduced) or not participate in the textbook provision and distribution circuits. These options impact on the role of publishing houses. Also, subject matter specialists (often university-based) may be part of State-led commissions for textbook assessment, or be contracted by publishers to produce textbook content. Teachers' choices of instructional materials are influenced by this kind of institutional dynamics, but not determined by them, since most teachers have access to an increasingly wide array of materials in digital formats. This complex and unorganized architecture builds up around each of the instructional components and makes it difficult to talk in terms of the simple centralization/autonomy dichotomy.

The broad range of actors involved in curriculum governance can represent a challenge to the alignment between different instructional components (Porter, 2002), which is considered desirable under the premise that poor coherence among these elements configure conflicting sets of demands on teachers and thus compromises education policy implementation (Fuhrman, 1993). Well-aligned systems, instead, provide common expectations to teachers through a coherent "curricular environment" of instruments intended to steer teaching (Valverde, 2009). This view is critical of policies based on a "hopeful pedagogy," where no deliberate efforts to achieve a coherent scheme are made (Atuhurra and Kaffenberger, 2020).

Alignment considerations add an additional layer of complexity to the design of curriculum governance. However, it can lead to the temptation of equating high levels of alignment with policies undermining teacher autonomy via centralized curriculum development. A closer look at policy options that can promote alignment shows this is far from being the only way to coherence.

Schmidt and Prawat (2006) consider alignment as a relevant criterion for curriculum development, but not a sufficient one. They stress the importance of working with a broader conceptualization of curricular coherence, which Schmidt et al. (2005) elaborate

further. This introduces a new layer of considerations pertaining to the internal architecture of curricular standards. Based on Bruner's definition of understanding, they define content standards to be coherent if they are "articulated over time as a sequence of topics and performances consistent with the logical and, if appropriate, hierarchical nature of the disciplinary content from which the subject matter derives" (2005, p. 528).

Another dimension of the internal structure of curriculum standards is brought up by Pritchett and Beaty (2015), who find out that many countries show small learning gains in children after several years of schooling (a situation to which they refer through the idea of "flat learning profiles"). They stress the importance of attending curricular pace as a relevant criterion: "if the official school curriculum covers too much, goes too fast and is too hard compared to the initial skill of the students and the ability of the schools to teach this can produce disastrous results. An overambitious curriculum causes more and more students get left behind early and stay behind forever" (2015, p. 280).

This perspective shows curriculum governance as a highly sophisticated policy realm made up of overlapping layers of technical complexity. The choice and design of instruments for instructional guidance, the network of institutional (state and non-state) actors involved in their design and deployment, the extent to which instruments are aligned with each other and the internal architecture of curriculum guidelines make up just a few of the multiple dimensions entailed in the technical design of curriculum governance.

But the question is not limited to the technical dimension. There is a political dimension that allows us to strike the final blow to the centralization vs. autonomy dichotomy. The extent to which governments build direct bridges with schools through listening and feedback mechanisms and the ways in which they open the game to plural participation in defining curricular priorities are part of this dimension. The State can provide detailed guidelines on how to teach and still give freedom to teachers in their choice, trying to introduce other policy instruments that build teachers' capacities for the judicious selection of these materials.

There are multiple alternatives and it is not possible to reduce them to such a binary dichotomy as centralization-autonomy. The analysis shows us that these are not separate paths but ingredients that are combined in different layers of curricular governance; in proportions that are not fixed but which, in the best of cases, are adjusted to the needs of the cultural and historical roots of every educational system and to the capacities and sense-making processes by teachers.

Besides, the dichotomy becomes weaker as governance itself shifts toward network-based structures made up of state and non-state actors and based on disparate sites, where the centralization-decentralization divides no longer captures the complex architecture of regulation. As Ball puts it, there is a shift toward a more polycentric state: "a controlled decontrol, the use of contracts, targets and performance monitoring to 'steer' from a distance, rather than the use of traditional bureaucracies and administrative systems to deliver or micro-manage policy systems" (Ball, 2008, p. 41).

A democratic and iterative position in terms of curricular governance need not be centralized or decentralized. It can escape top-down imposition and control through capacity-building, plural dialogs, evidence-informed decision making, teacher-led curriculum development commissions and so many other non-dichotomous alternatives.

Conclusions

Vertical curriculum models have gained increasing weight in recent curriculum debates in many countries. There is a temptation to centrally regulate the curriculum through different policy instruments: standards, textbooks, centralized tests, or scripted lessons. This curriculum governance shift clashes with professional autonomy and cultural diversity.

Franklin Bobbitt's classic text already posed this dilemma in 1918: Should a curriculum be envisaged as the blueprint (map, journey, destination) that underpins (and predates) the day-by-day activities of schooling? Or should a curriculum be envisaged primarily as the "consciously directed training experiences" themselves? (Bobbitt, 1918, p. 43).

In this text we open multiple questions to escape the simplifications of the dilemma in three ways. In the first place, looking for the complexity of the curricular government. There are different policy instruments, diverse actors and technical layers of curricular design. An overemphasis on centralization may be associated with perspectives more focused on accountability as external pressure for improvement. It is possible to overcome this perspective with the analysis of the sophistication of the field of curricular government, taking the lessons of internal organization of the curricular models that show to have better results in terms of student learning (Cohen and Spillane, 1992; Elmore and Sykes, 1992; Schmidt et al., 2001; Valverde, 2009).

Second, it is important to assume the complexity of the curriculum enactment process. A simplified view of centralization can fall into the trap of thinking that the rules are applied by sheer force. This ignores the weight of cultures and traditions that may be more oriented toward the fulfillment of state mandates or toward the diversity of interpreting practices in schools. As Remillard and Heck indicate: the education system is a map of "places within the system that curricular elements are translated and transformed" (Remillard and Heck, 2014, p. 705). Everywhere in the diversity of situations of learning there are disputes, interpretations and transformations of the curricular mandates.

Third, the centralization dilemma requires recognition of the identity and agency of teachers. There is a repeated lesson in curriculum policy studies: programmatic curriculum planning affects classroom curriculum planning only if teachers understand and employ the adopted framework and materials (Snyder et al., 1992). A democratic curriculum is one that consults teachers in their work context to adapt the curricular text to reality and to give a voice to the actors of the educational system.

These three escapes from the dilemma allow us to take the lessons of the history of centralized curriculum models and rethink them in the 21st century. We live in a time of wide cultural diversity, constant change and an uncertain future. The curriculum

cannot be something fixed or excessively external to teacher's realities or alien to the culture of a country. Neither can we ignore the importance of accountability, alignment and systemic coherence, as different studies teach us. Finding the balances, mixes, and blends is a central challenge of curriculum governance today.

The rise of curriculum reform in Europe (1500–1800s)	28
How curriculum reform changed scientific meaning at the turn of the 20th century	30
Revolutionary approaches and the reinvention of curriculum in the 21st century	31
References	33

Curriculum as an institutional arrangement engages networks of actors, including public ministries, agencies, textbook publishers, universities and colleges, unions, school practitioners, and public interest groups (Sivesind and Westbury, 2016). In this context, both public and private school authorities formulate curricula to coordinate their education systems. Formal curricula are traditionally presented in the form of books or booklets and conveyed via web pages or electronic platforms. In any form, curricula can mediate general principles and guidelines, overall goals and objectives, and content that is, what to teach and learn over a period (Karseth and Sivesind, 2010). They can also present evaluation standards and assessment criteria that help decide when students improve their learning and complete a study course (Scholl, 2012; Westbury, 2007).

When school authorities reform their programs and study courses, academics develop knowledge, relevant in teacher education. Here, students learn about past, present, and future orientations to reform work and how to make sense of curriculum in everyday school practice. Academics are also involved in curriculum implementation within and across policy realms and levels (Priestly et al., 2021; Wahlström and Sundberg, 2017). Through a branch of activities and by various mandates and purposes, educational researchers deploy knowledge in various forms, which, over time, has created a field known as curriculum studies (Hopmann, 2015).

Currently, experts in the field of media and technology develop perspectives on education that challenge this study field. For example, Collins and Halverson (2018, p. 67) argue that technology-based seeds of new systems revolutionize education by innovations and developments that allow for a new type of flexibility in pedagogy and learning that outpaces both curriculum and schooling as traditional knowledge fields. They contend that the old curriculum tradition corresponds with a “grammar of schooling” that does not resonate with rationales, needs, and expectations of how to educate children and adolescents within the 21st century. By considering the 20th century industrialization of North America as the breaking shift toward a modern school system, they ignore the fact that various modes of educational reasoning modernized public education in Europe long before Americans invented their mass education system.

This chapter aims to elucidate the various modes of reasoning that have legitimized curriculum reform and public schooling across centuries. It sheds light on how curriculum reform has developed into an institutional arrangement of administrations and schools in both Western Europe and North America. The chapter provides historical insights into relevant concepts and perspectives to understand various rationales for curriculum reform, both about the way reform gained interest by school authorities in Europe before the 20th century and how curriculum turned into the vocabulary of reformers in the United States and elsewhere over the two last centuries.

I begin with a historical review of the first European efforts to develop comprehensive school reforms legitimized by a philosophy of *Bildung* (Sivesind, 2021, 2022; Sivesind and Luimes, 2017). Interestingly, the idea of general schooling appeared in academic literature in the 16th century before state administrations became the site for organizing reforms that implied curriculum renewals. In the second part, I present how reform became a key feature of North American education and how historical and empirical conceptions of curriculum reform emerged in the 20th century. Reform efforts in the United States during the early and mid-20th century emphasized the significance of disciplinary knowledge and thereby ideational streams of thought that were invented at European universities during the 16th and 17th century.

In the third part, I discuss whether the modes of reasoning that have evolved through history are relevant to the 21st century. As mentioned, some researchers today claim that curriculum studies are out of date due to new technology and media that revolutionize education. I argue, however, that without acknowledging the democratic value of curriculum reform as an institutional arrangement, it is almost impossible to understand how public schooling can serve the democratization of society. Thus, I conclude that both for continuing to develop democratic societies and to handle various types of social, cultural, political, and educational problems, research on curriculum reform is highly relevant. This also means considering the intended and unintended impacts of technological innovations on public schooling, which is a topic that further research needs to examine more closely.

The rise of curriculum reform in Europe (1500–1800s)

Comparative history studies examine how ideas and institutions of relevance for public schooling have evolved over centuries in concert with societal developments. They illuminate how curriculum embraces ideas of public schooling and explore how schooling

develops in concrete and diverse forms (Hamilton, 1989; Hopmann, 1999, 2007; Künzli, 1998). Broadly seen, researchers in this field consider historical changes in curriculum practices as movements underpinned by political, public, and academic ideas and traditions (Kliebard, 1992; Schubert, 1986; Tanner and Tanner, 1990). Also, researchers review structural and purposeful changes in teaching practices as an important dimension of curriculum and schooling.

Curriculum implies a systematic and structured educational practice. As an institution, it lasts over a period different from a cursus where students do not necessarily comply in accordance with a planned study course (Hamilton, 1989). Researchers, such as Reid (1999, p. 97), consider curriculum as an institution that is characterized by both a beginning, a process, and an end. The beginning can be the enrolling procedures of including students in a program, the process may well reflect teaching and learning activities in the classroom, and the end can be the final exam or another confirmation that signalizes that the study course is completed.

As already noted, curriculum reform as a modern idea draws on classical modes of reasoning that include conceptions of a public order (Hopmann, 1999; Weniger, 1999/1952). A semantical analysis of reform helps unravel the meaning of this concept. At first, intellectual scholars used the term revolution to capture a particular order of the world, as the concept reflected a natural order as much as a societal one. According to Hansson (1991, p. 7), the term revolution originated from medieval astronomy, referring to the regular return of planets along their orbits in space. Against this backdrop, reform means to reproduce the original form. Hansson (1991) emphasizes that the Christian Reformation leading to Protestantism at the beginning of the 16th century received its name from the concept of reform. In this context, reform was meant to reinstate a form of God-given order. Although actors were considered as individuals with a free will, they were not in a position to change the order of the Genesis and could not change the structural basis for what to preach and teach. The catechetical method of, for example, the Lutheran contract school that resulted from the Protestant Reformation was founded on this conception of a structural order (Künzli, 1998; Sivesind, 2021, 2022).

At the same time, a reconstitution of the church during the Protestant reformation aimed at accomplishing a practical order that substantiated rhetorical principles of creating trust, which in the church related to the interaction between the priest and his congregation. The theological doctrine allowed for a worldly relationship as well that were human by being informed by reason. Thus, rationales beyond a predetermined order evolved along with the development of Protestantism that influenced national constitutions as well as public schooling in, for example, Germany, and the Nordic countries in Europe (Tröhler, 2012). It is in this new context that reformists developed ideas of reform and *Bildung* that enlightened a theory of teaching called *Didaktik* that conceptualized schooling beyond a theological world view (Künzli, 1998).

The reform history in Europe serves as a brilliant example of how curriculum and reform first entered the vocabulary of academic scholars in education. Because of the new possibilities in publishing text materials arose in the 16th century, scholars created textbooks that shaped teaching and learning in substantial ways. These materials, as well as the organization of teaching activities, created modern conceptions of curriculum content. For subjects other than religion, university professors outlined scientific disciplines of significance for educating students (Nordkvelle, 2011). In European states, the invention of print media resulted in new knowledge that also influenced elementary schooling during the 19th century. New books for teaching were written along with the growing number of schoolhouses and school buildings (Sivesind, 2008).

One of the classical texts from this period is Ratke's (1664/1967) book that inspired educational thinking and reasoning, relevant for curriculum and teaching. As an enlightenment scholar, Ratke wrote about a system of grades that structured a public school system along with the Latin notion of *Currere* (eng. to run). Also, the philosopher Comenius (1659/2007) wrote his *Didactica Magna* in this period, which drew on encyclopedic reasoning, including ideas about educational governance besides moral reasoning of significance in teaching practices (Norlin, 2020). Thereafter, in the 18th century in Europe, noble people, including popes and kings, began organizing elementary teaching for children. Their highly elitist projects transformed over time and turned into public schooling under the motto "education for everybody". This expression was inspired by Comenius' work and his ideas of *Allgemeinbildung*, which aimed at cultivating the entire population in a country (Klafki, 2000).

In German states, it became essentially important to establish and regulate compulsory schooling along with the invention of state administrations. In the Nordic region, curriculum-making processes were first considered part of law revisions that were legitimized by religious reforms that resulted in new regulations and ordinances of the state as well as the school. These law revisions first gained their legitimacy through the approval of the monarchs who authorized their rationales on a religious manifesto. More generally, reforms became decisive for building and authorizing public systems or sectors that differed from larger, more dramatic changes in society associated with revolutions and wars. Moreover, during the century, the adoption of national constitutions in various parts of Europe legitimized powerful steps toward establishing compulsory schooling by law (Tröhler, 2016).

During the 19th century, school owners used texts and other materials as powerful resources to differentiate curriculum reform into various subject areas. In addition to textbooks, collections of materials, such as stuffed animals, were used to bring the material to life for students. This form of secularization legitimized encyclopedic knowledge as part of school reforms for both elementary and secondary schooling. It was no longer just the law and religious texts that served as a canon, but texts about nature and history in general. This idea served to implement Friedrich Schleiermacher's (1768–1834) hermeneutic doctrine of what he considered an "art". This form of hermeneutics—that is, an approach of text interpretation that reflected upon the objective basis of sequencing and selecting content beyond what is legally and religiously predefined—became essentially important for legitimizing curriculum reforms in Europe.

Along with the development of this art, an evolving public has acquired the right to legitimize changes. As a result, regulations did not arise out of a natural right, nor were they constituted by laws alone; rather, they arose “out of right, established by relations”, to use Lorenz von Stein’s formulations from 1852 (Koselleck, 1985, p. 63). By a dialectic mode of reasoning, reform makers emphasized encyclopedic ideas that shaped the content of curriculum reforms and an increasingly number of subjects. The explosion of content that emerged during the 19th century demonstrates why formalized curricula with canonical knowledge became so important. A core aim was to rebuild relations between the state and the people. Throughout the next centuries, this arrangement became institutionalized by European states, which were dependent on political, professional, public legitimacy, and support to establish themselves as democratic institutions (Sivesind, 2008). In England, private institutions also gained legitimacy with a public right to provide education for the masses.

How curriculum reform changed scientific meaning at the turn of the 20th century

Despite the combination of administrative and academic initiatives to create a “school for all” that drew on scientific reasoning and aimed at developing a societal-relevant school system, researchers in the US argued for rationalizing the curriculum by reform during the 20th century. In the beginning, cultural and social differences between those born into noble families, those who belonged to the bourgeoisie, and those who were poor without titles and occupations marked societies as highly segregated. Moreover, conflicts and insecurity resulting from wars in continental Europe brought about immigration in the United States, which again resulted in a highly cultural-heterogenic society in the country. At that point in history, industrialization and new beliefs in technological progress created hope for a better future as well as ideas about systems that could make education more efficient.

Of key significance for developing systematic thinking about curriculum was as Kliebard (1988a, p. 45) interpreted: the “systematic thought about education generally” that implied general consideration of historical conditions. He points to the rising population of high school students that doubled over a forty-year period, every decade after 1890, as a core reason for curriculum developments. Moreover, transformations in American society resulted in a wish for an Americanization of immigrants that turned into a new vision of schooling. Professors in education who participated in the National Education Association (NEA), which became an important meeting point for national discussions in education, also influenced curriculum development, and in particular by the initiation of the Committee of Ten.

The commission was mandated to deal with the issue of heterogeneity in high schools and the question of how this school program should prepare students for enrollment in colleges. Under the direction of Charles W. Elliot, the commission argued for a highly disciplined curriculum based on the conception that everyone could learn academic knowledge independent of their cultural and social background. Therefore, no separate tracks were needed for college admission. Another prominent scholar in this period was G. Stanley Hall, who was critical of the conception that every student should be taught school subjects in the same way regardless of their destination. Thereby, he argued for “curriculum differentiation” (Kliebard, 1988a, p. 49). Also, he did not accept Elliot’s argument that preparation for college is a preparation of life, and in the end, it was Hall’s perspective that won out; that is, the goal of public schooling for adolescents was to prepare students for practical and social responsibilities rather than to accomplish intellectual attainment.

Together with a steep growth of knowledge that outpaced traditional subject scholars, John Franklin Bobbitt, in agreement with Werrett W. Charters and David Snedden developed a set of basic principles of a “scientific curriculum”. This movement implemented ideas of scientific management that Fredrick Winslow Taylor promoted in the field of organizational studies. In this era, curriculum goals were perceived as a natural phenomenon that could be discovered by observing skillful human beings and their ways of making elementary operations into an efficient series of movements. Kliebard 1988a summarized this expert notion of curriculum reform:

Curriculum development became an effort to standardize the means by which predetermined specific outcomes might be achieved. Success was judged by the extent to which the actual outcomes matched the predictions.

Kliebard (1988a, p. 51).

However, with increased urbanization, known reformists, such as John Dewey (1858–1992), also started to write about ways to deal with the problems of men (Dewey, 1946/2014). Although he failed in setting the agenda for curriculum research in his own country, as Bobbitt and Charter did (Waldow, 2015), Dewey inspired reform work far beyond the borders of the United States through his many projects and publications. A core theme related to the societal conditions that served as a frame for Dewey’s theoretical deliberations (Lundgren, 1989). A possible reason for the variation in his outreach is the fact that Dewey developed his pedagogy in a context where reforms and plans had a different authority compared with what was the case in European states, where school content was selected by professionals in collaboration with state officials. Nonetheless, for the American case, both societal and scientific reasoning and disciplined knowledge become essential dimensions for selecting and organizing curriculum knowledge. Moreover, curriculum reform did not merely refer to state public schooling but to a highly differentiated practice of various reform initiatives.

American curriculum projects that developed during the early 20th century and onward selected curriculum content through scientific rationales, an approach that the federal government intensively urged after the Sputnik shock in 1957. Then, the Soviet Union accomplished its mission and scientific advancement of sending the first satellite, Sputnik-1, into the space with a dog, Laika. Scientific reasoning was already a decisive basis for legitimizing school content in American curriculum theory at that moment. Dewey, for example, also included assessment by scientific rationales as a key to students' learning, which differed from German scholarship, which emphasized practical judgment by teachers in schools (English, 2013).

The Industrial Revolution and an increasing population in the cities were, above all, the core explanations why compulsory education developed into a mass schooling system in the United States at the beginning of the 20th century. Curriculum reform reflected societal changes that affected teaching and learning, as well as the way educators communicated about reforming programmes and courses. Social aspirations of various kinds and assessment criteria for selecting students for various programmes and study courses served as important parameters for organizing public schooling in America (Labaree, 2012). Through assessments and examination, geography, age, ability, former academic achievements as well as needs, motivations, and interests served as criteria for differentiating students in various grades and classes. These criteria were important for thinking and writing about curriculum reform as well. Thus, curriculum as a concept reflected the architecture of the education system, known as the "grammar of schooling" (Tyack and Cuban, 1995; Westbury, 1998).

Internationally, different pedagogies referring to various types of curriculum reform developed as parallel modes of thought during the 20th century. This phenomenon can be explained by the fact that there were no clear linkages between curriculum reform as an institutional arrangement across national borders and how schools responded to new regulations. Moreover, curriculum reform was also considered an expression of various cultural ideologies. This conception resulted in views of contemporary reforms in the North American tradition as a conscious move between poles of value-oriented ideologies, conceptualizing changes as "pendulum swings" and as "cycles that ebb and flow" (Cuban, 1990, p. 7).

Short-lived reform cycles have been the subject of many reports and analyses in the field of curriculum history and reform. Kliebard (1988b) suggests that one of main reasons for the steady change of reform orientations, or the ebb and flow of "curriculum fashions", is the actual absence of purpose of curricular decisions that characterizes many reform efforts. This again means that structural reforms of merely legislative or legal order do not necessarily correspond with the core purposes of curriculum ideologies reflected by the philosophy that legitimize curriculum reforms from a cultural point of view.

Moreover, Cuban (1990) uses "waves" as a metaphor for explaining how teaching and learning in schools are targeted by curriculum reform, however, not necessarily leading to a transformation of curriculum practices. He writes about school districts that initiate large-scale reforms on a national basis, but like a wave, they generated only surface change. Cuban (1990, p. 9) also observes that administrators turn "religiously to school-based solutions for national problems" while teachers continue teaching their subjects to meet expectations within the public domain. Therefore, reforms are frequently reintroduced to restructure education and reorder the inner lives of schools, however, without necessarily accomplishing their missions and goals by changing classroom practices.

Revolutionary approaches and the reinvention of curriculum in the 21st century

By investigating discourses on curriculum reform, one discovers how scientific and technological reasoning frame modes of reasoning to close the gap between reform aspirations and practices. Today, international nongovernmental organizations and expert networks serve as sites for authorizing curriculum programs in which assessment standards and competence goals serve as a common core. Many efforts to create international programs with implications for curriculum reform across nations have resulted in several definitions of competencies and skills for the 21st century. Numerous international organizations use competency and skills for the 21st century as a scientific-normative expression of what human beings should achieve through their life-course to accomplish work-life demands and societal transformations beyond what teachers can teach in a normal classroom.

The scientific effort to improve learning and instruction developed in a Cold War context and resulted in large reform programmes in the United States and elsewhere, motivated by the Sputnik shock (Tröhler and Lenz, 2015). However, since then, expressions of scientific-legitimized curriculum reform efforts have reflected paradoxical and conflicting interests, as acknowledged by UNESCO in the early 1970s. Faure et al. (1972–73) described the educational traditions and legacies of the past that put focus on both literacies and humanism, grounded within a scientific rationale for developing education within a learning society. The following quote demonstrates how the commission, consisting of ministers and experts, characterized the mastery of learning as a perplexing purpose of education:

For these reasons, the commission considered that it was essential for science and technology to become fundamental, ever-present elements in any educational enterprises for them to become part of all educational activities designed for children, young people and adults, so as to help the individual to control not only natural and productive forces, but social forces too, and in so doing to acquire mastery over himself, his choices and actions; and, finally, for them to help man to develop a scientific frame of mind in order to promote the sciences without becoming enslaved by them.

Faure et al. (1973/1972).

To argue for the development of “a scientific frame of mind in order to promote the sciences without becoming enslaved by them” (Faure et al., 1973/1972) seems to be one of the dilemmas that policymakers, professionals, and even populations could face concerning this policy agenda. This concern is entangled with international large-scale assessments that draw on particular research methodologies and scientific reasoning to legitimize curriculum reforms in the 21st century (Sivesind, 2013).

A range of programs launched by international organizations have emerged along reform efforts, such as the programs of comparative studies from the 1960s through the 1980s organized by the International Association for the Evaluation of Educational Achievement (IEA) and international assessments by the Organization for Economic Co-operation and Development (OECD), which entered this comparative field during the 1970s (Sivesind, 2019). Today, several research reviews define what experts mean by “competence” and “21st century skills” across areas and contexts (Binkley et al., 2012; Dede, 2010; Kereluik et al., 2013; Tahirsylaj and Sundberg, 2020; Voogt and Roblin, 2012). National and international organizations present “competence” and “skills” as if they were the most relevant to master in a “lifelong” perspective, a term that suggests that each person has an imperative responsibility to see him or herself as an active lifelong learner and to act accordingly. Moreover, these initiatives have various forms of support in different parts of the world (Nordin and Sundberg, 2016), depending on conditional recourses (Hopmann, 2003), political decision-making capacities (Tahirsylaj and Sundberg, 2020) as well as shared historical memories of regional and local reform initiatives (Sivesind and Karseth, 2019).

Manifestly, there has been an intensified focus on competence and learning within large projects that prospect the future school beyond 21st century skills, cognitive, and social skills that are essential to success (Hilt et al., 2019). The same goes for innovation and integration brain development—an optimal time to help young people shape their intelligence, identity, and personality. As Restad and Mølstad (2020) have shown, the focus has recently changed from a general competence-based orientation of school reforms with emphasis on literacy within and across school subjects to a more psychological orientation of the inner life of students, which draws attention to deep learning and the performance of social and emotional skills.

There is also a shift from competence built into aims and objectives for teaching and learning to a more specific focus on attitudes associated with certain values (e.g., OECD, 2020). More specifically, “deeper learning” is the process of preparing and empowering students to master a set of outcomes through learning processes that are characterized by a set of quality features (Bellanca and Boss, 2015; Mehta and Fine, 2019). The topic is not described as entirely new by educational scholars, but considered as much needed by think tanks and other stakeholders because of political and societal problems, such as the achievement gap that is not diminished by traditional school systems (All4Ed, 2022). Thus, it is interesting to investigate the way this and similar concepts and strategies are used by policymakers and experts to determine if and how curriculum reform efforts in contemporary systems fit with old styles of reasoning.

Even though current discourses are characterized by a constructive discourse of creating and recreating new curriculum reforms for the sake of democratizing society, the “grammar of schooling” as a system that resists changes serves as a strong narrative that researchers and experts criticize. Currently, revolution seems to be a scattered concept among those who promote paradigmatic changes in education and would like to reinvent and renew curricula along with novel technological innovations. Rather than focusing on curriculum reform and affiliated pedagogies, authors like Collins and Halverson (2018, p. 67) argue that technology-based seeds of new systems revolutionize education and thereby outpace both schooling and education research. The authors claim that technological revolutions alter not only the lives of children and adolescents but also every aspect of work that demands a paradigm shift in education.

Collins and Halverson (2018, p. 49) refer to modernization processes of the education system in the United States in the first half of the 19th century and Horace Manns’ education visionary for creating a social cohesive system through state involvement in education. They also reference the rationales of elitist education of the Greek gymnasium, the medieval university, and the English grammar schools as well as the invention of the printing press, the reformation, the American and the Industrial Revolutions as core explanations for the rise of universal schooling in the United States. Despite being aware of this historical trajectory, the “grammar of schooling” is considered more or less fixed without a capacity to integrate new technology as such.

A possible reason why the authors look upon the grammar as more or less fixed without a potentiality to deliberately change education in accordance with contemporary demands is the empirical fact that a system, where the state serves a passive role as a school provider, has largely been replicated as a curriculum model in large parts of the American education system. The first signs of this model date back to the mid-17th century, when Calvinists adopted formal laws for general education (p. 50). Horace Mann serves as an example of a movement in New England, where the state became a provider of general education. However, along with progressivist reformers, Collins and Halverson (2018) consider the Industrial Revolution as the prime driver that transformed “the universal schooling movement from an evangelical movement to a practical necessity” (p. 53). Thus, the Industrial Revolution is considered the key to understanding how society became modernized in the United States in the 20th century and how a “grammar of schooling” established procedures and patterns that the authors consider as not congruent with current demands.

However, in their critique, Collins and Halverson (2018) overlook the variation of traditions and modes of reasoning that legitimized schooling as a democratic project beyond the evangelic movement. Thereby, they base their view on a highly biased narrative of curriculum reform and schooling. For example, in Norway and Denmark, which belongs to the Nordic part of Europe, nation states developed education systems in which parents were considered the prime responsible actor for taking care of children’s upbringing. The contract-school model that arose during the Protestant Reformation legitimized this idea (Sivesind, 2021). In this system, monarchies developed their education systems not merely by preparing “people for their proper place in the social order” nor for preparing “students to choose public over private interests”, as claimed by Republican leaders in the United States, referenced by Collins and Halverson (2018, p. 53). Rather, the education system was developed as a pragmatic project to ensure

children's education in their own rights, which was legitimated by progressive teachers and intellectual reformists in the early 20th century (Sivesind, 2008). This is particularly true for monarchies that democratized their systems before industrialization changed their economies into a new societal order (Sejersted, 2011).

Conclusively, due to various modes of reasoning that legitimized public schooling during the 20th century and because of different forms of administrative control across countries and continents, there are no such thing as one "grammar of schooling", neither in Western Europe nor in the United States. Although more post-modern approaches to reforms have made the world into a more complex space, one may still consider curriculum reform as a place-based phenomenon with a highly particular history and therefore of relevance for developing public schooling in the 21st century. For this reason, researchers argue for re-inventing schools, the curriculum, and reforms within a global perspective (Bangs et al., 2010; Priestley and Biesta, 2013; Takayama, 2010).

Westbury and Milburn (2006) argue that "core issues policy-makers have faced have been typically set in a time and place, and framed within the discourses of their immediate worlds". Thus, the life-world of both policymakers, teachers, and all other parties are all important for how curriculum reform evolves and transforms (Goodson, 2019). I argue that digitization processes and the active involvement of edtech companies in education challenge traditions as well as curriculum reform daily (Williamson, 2017). Still, it is also of high relevance to rethink the novelty of technology in education:

Given the breathless enthusiasm with which new learning technologies are introduced, one of the most useful dispositions in evaluating edtech is to regularly ask the question, "What's really new here?"

Reich (2020, p. 21).

This question may lead to a renewed interest in the ways technologies and media interact with curriculum reform to handle social, cultural, political, and educational problems in contemporary school systems.

Introduction

Curriculum is both a key concept in the study of education and a concept that is deeply contested. To some, the term refers to the seemingly objective knowledge content and skill-set of a program of educational study. In contrast, Apple understands curriculum as a profoundly political phenomenon: “... always part of a selective tradition, someone’s selection, some group’s vision of legitimate knowledge” (1996, p. 22), while Todd describes curriculum as “the symbolic raw material” of education (2001, p. 446). In attempts to pin down and control the slippery concept and practice of curriculum, governments globally have introduced prescriptive curriculum policies. Reform of curriculum policy does not only affect the curriculum message system,¹ it also impacts on the message systems of pedagogy and assessment which interweave symbiotically with curriculum. This is important because it is through the three message systems in schools that dominant social groups construct, select, classify and relay what is constituted as socially legitimate knowledge, values and attitudes (Bernstein, 1971). So, for example, the selection of knowledge in a curriculum specification influences its pedagogic enactment, its assessment and the values entrenched within that knowledge.

Such is the significance of curriculum policy reform in driving change in pedagogy and assessment in recent years, that Gerrard and Farrell describe curriculum policy as “a cornerstone of educational governance” (2013, p. 4). Taking this a step further, Lingard et al. (2013) identify “curriculum as systemic policy” (p. 549). In other words, curriculum policy-effects extend into classrooms through the enactment of curriculum knowledge, pedagogical practices, student-teacher relationships, school spaces, time and cultures, assessment processes, as well as through the very identities of participants. Since curriculum forms such an important site of political power in education, analyzing curriculum becomes a key concern. Hence, the central focus of this article is the language through which curriculum is constructed and the discourses it evokes.

¹Bernstein describes the three message systems of educational knowledge as curriculum, pedagogy and evaluation: “Curriculum defines what counts as valid knowledge, pedagogy defines what counts as a valid transmission of knowledge, and evaluation defines what counts as a valid realization of this knowledge ...” (1971, p. 47).

In the past, curriculum research and academic texts were located in the curriculum studies tradition, with the aim of supporting curriculum planning and development (Tyler, 1949; Schools Council, 1970; Goodlad, 1979; Kelly, 2009). While these curriculum planning/development models and perspectives can be adapted for analytical purposes, curriculum analysis did not form their *raison d'être*. More recently, education policy analysis frameworks have been adapted for curriculum analysis, such as the policy cycle model offered by Bowe et al. (1992) and Rizvi and Lingard's key policy analysis questions (2010, pp. 54–56). In addition, curriculum researchers have developed particular approaches to analyze curriculum in specific international contexts (Chun-Lok and Wing-Yan, 2009 Hong Kong; Roofe, 2020 Jamaica; Singh et al., 2013 Australia; Priestley and Sinnema, 2014 Scotland and New Zealand; Winter, 2018 England; Macedo, 2011 Brazil; Gleeson et al., 2020 Australia and Ireland; Fitz and Nikolaidis, 2020 US; Ghebru and Lloyd, 2020 Ethiopia; Nomura, 2017 Japan). In spite of these theoretical and empirical tools available for curriculum analysis, a gap exists in terms of a critical systematic text-analytic framework of value to students, scholars and practitioners across a range of educational phases, from early years to schools, through to adult/Further/Higher Education, and across different national contexts. The framework offered in this article aims to fill this gap.

The contemporary demand for such a framework arises primarily from the need to identify and challenge the seemingly innocent purveyance of neo-liberal education policies globally through curriculum reform and its impact on social justice (Lingard et al., 2013, p. 541). Ball (2008) describes how supranational organizations like the OECD, World Bank and EU drive global policy reform to embed new processes of educational governance through accountability measures to promote the economization of education and human capital formation. In the advancement of curriculum reform, common policy technologies of governance, consisting of the market, new public management and performance are operationalized (Ball, 2008, p. 42). However, shaped by national "vernacularization" (Lingard, 2006), these policy technologies find expression in particular ways in different countries. National curriculum reform policies manifest in the form of curriculum texts and discourses. For the purposes of this study, these consist of curriculum policy texts, curriculum specifications, textbooks, test/examination questions, worksheets, teaching artifacts, online teaching material, but always interpellating and/or co-occurring with other texts (intertextuality) and the discourses contained within (interdiscursivity). A critical analytical framework like the one offered here allows education professionals to deconstruct these texts and discourses to unpack and unmask how language and images expose the very power relations, values, politics and ethics at work in curriculum construction, meaning and enactment at global, national and local scales.

The context described above demonstrates the need for a clear, flexible, accessible and critical curriculum audit and deconstruction framework to support Higher Education (HE) students and staff and school/college teachers engaging in curriculum analysis/critique. Educators require a rigorous approach to investigate curriculum processes and motivations via the language, power, discourse, ideology and epistemology embedded in texts. While offering a generic and comprehensive audit tool which can be applied across a range of curriculum texts in any geographical location, the framework is not a technical, one-size-fits-all mechanism to be applied in a linear, step-by-step fashion. Instead, it requires the curriculum analyst to research the historical, political, and cultural context of the curriculum under investigation, and to make decisions about the focus of the analysis, depending on their own curriculum context and on their own reflexive stance in terms of their positionality.

Following this introduction, the article discusses insights from the literature (divided into a focus on curriculum contexts and on a critical discourse studies (CDS-oriented) approach) before presenting the framework itself. Then the framework is discussed, through an illustrative case study curriculum in the secondary school in England. We end the article with our final thoughts.

Within the article, we aim to foster cognizance by education researchers and practitioners of the ways in which potential construals in curriculum texts and enactments can obscure circulations and articulations of power. Through this, we aim to reveal the ways in which these articulations can impact upon teachers and learners. Our framework focuses on the investigation and elucidation of the means by which textual practices should be seen to be historically, ideologically and politically located social practices. The critical curriculum analysis framework (CCAF) offers an analytical structure and process for interrogating curriculum discourses. In doing so, we aim to offer those engaged in curriculum analysis the means to deconstruct the language, and its ideological essence as construed through discourse, of curriculum avowals.

Curriculum context

Before introducing the approach to discourse analysis adopted in this article and the critical curriculum analysis framework itself, it is important to situate curriculum, albeit briefly, in the global setting. One starting point is Sahlberg's Global Educational Reform Movement (GERM) (2011, 2015) which illustrates the impact of globalization and neo-liberalization on curriculum. Sahlberg describes how supranational organizations, corporations and venture philanthropists invest finances, business concepts and practices into global education systems (2015, p. 143), to propel them toward an economic, commercial mode of operation. Along with international standardized student tests like PISA as a key driver of curriculum reform, the impact of GERM around the world includes externally prescribed, mandatory curricula; prioritization of core subjects of literacy, numeracy and science; outcome-based assessment, standardization of performance through benchmarks; and test-based accountability, expressed in

school performance tables and driven by competition between schools for student recruitment (2015, p. 145). Such technicization of curriculum has involved the re-fashioning of traditional academic curricula into competency/skill-based curricula which aim to prepare students for the 21st century global knowledge economy (Savage, 2017, p. 158). Unsurprisingly, national policy players mediate global curriculum reform tendencies in different ways in different national spaces as curriculum policies are “borrowed” and “travel” between countries. The resulting policies are influenced by political, economic and historical conditions particular to each nation. Taking the cue from Appadurai, Lingard describes this process as “vernacularization” (2000). But shifts to competency-based curricula have met with a backlash around the world in the form of the claim that it forces the “downgrading” of disciplinary knowledge at the expense of generic learning skills, with the effect of damaging students’ life chances (Rata, 2012; Young, 2007).

This claim has given rise to the curriculum debate over “powerful” versus “everyday” knowledge. Proponents of “powerful knowledge” posit that disciplinary or subject knowledge is “powerful” because it is conceptual, systematic, specialized and takes students beyond their personal experience. As such, they claim, it is distinctive from everyday knowledge and should be an entitlement of all learners because it offers opportunities for educational attainment and social mobility by providing a more reliable and objective foundation for understanding the world than knowledge arising from students’ own experiences (Young, 2014). On the other hand, opponents argue that powerful knowledge emphasizes the cognitive realm and neglects social justice issues (Zipin et al., 2015). Beck points to tensions around inducting “disadvantaged” students into an esoteric specialized epistemology founded on a minority conception of “high culture” (2013) and in a similar vein, Catling and Martin (2011) state that powerful knowledge neglects learners’ “ethno-knowledges” as a learning base for pluralist epistemologies. These discussions are enriched via Rudolf et al.’s thesis that powerful knowledge erases the power relations of colonialism (2018). Opportunities to consider the pros and cons of powerful knowledge arise later in the article in the case study application of the CCAF. Before introducing the case study, an introduction to the critical discourse studies (CDS) approach to curriculum is needed.

Curriculum from a critical discourse studies (CDS) perspective

As Flowerdew and Richardson (2017, p. 1) note:

CDS is an interdisciplinary approach to language in use which aims to advance our understanding of how discourse figures in social processes, social structures and social change.

Building on the field of critical discourse analysis (CDA) (Fairclough, 2003), CDS-oriented discourse analytic tools, such as our own, allow for more systematic attention to be paid to the macro and micro linguistic features of the textual articulations of curriculum. Following Fairclough, Hyatt writes:

... relationships of texts, practices and ideologies to social structures, processes and interrelationships should be seen as modalities of power and can be more systematically investigated (2013, p. 44).

CDS draws its linguistic foundations from Halliday’s (1985) systemic functional linguistics, which emphasizes the centrality of viewing language within the contexts in which it is produced and utilized. In doing so it offers affordances for the interrogation of the ways in which language and power interrelate, and the manner in which language is implicated in other social relations, processes and the social actors involved therein.

For us, the value of using a CDS-informed approach to the analysis of curriculum lies in its potential for conceptualizing the realization of curriculum as a site of struggle. The processes of construction and representation of curriculum are discursive, and so our approach seeks avenues by which such constructions can be deconstructed and then potentially reconstructed in more socially equitable forms. Following Gee (2000, p. 197), we view discourses as:

... socially and culturally formed, but historically changing, ways of talking and writing about, as well as acting with and toward, people and things. These ways are circulated and sustained within various texts, artefacts, images, social practices, and institutions, as well as in moment-to-moment social interactions. In turn, they cause certain perspectives and states of affairs to come to seem or be taken as normal or natural and others to seem or be taken as deviant or marginal.

CDS’s orientation to interdisciplinarity allows the analysis of curriculum to be approached in dialogue with other disciplinary lenses and frames. Its semiotic focus on construction and representation through language and other modes allows for the unclinking of such representations of social structures and events which themselves are mediated “through social practices—forms of social

activity, which constitute and, in turn, are constituted by, fields, institutions and organizations in a dialectical relationship” (Hyatt, 2013, p. 45). Such a nexus of social practices finds its articulation through discourses, and a CDS-aligned approach offers the curriculum analyst a systematic framework to uncover how curriculum articulations represent particular worldviews. As such it can orient those on whom curriculum policy impacts to specific understandings of relationships, identities and institutions—and to unmask the relations of power that mould and characterize these discursive constructions and representations through their co-option of language and other semiotic modes.

We contend therefore that our critically-oriented curriculum analysis framework can elucidate an engagement with curriculum texts, where such texts are viewed as the product of recurring contestations “between contenders of competing objectives, where language—or more specifically discourse—is used tactically” (Fulcher, 1989, p. 7). We next introduce the CCAF before putting our claim to work in the case of the Geography curriculum in England.

The critical curriculum analysis framework (CCAF)

For the purpose of this study, we understand curriculum as multi-faceted and dynamic: as text and/or process and/or discourse. It occupies spaces—of production, influence, recontextualization (from the policy field to the educational institution) and of enactment. Regardless of form or spaces of occupation, curriculum policy and curriculum *per se*² in our minds are always and already steeped in values and relations of power, and are subject to influences both beyond the national realm and in the processes of classroom enactment. The diagram below shows the constituent parts of the framework.

Before investigating the framework in more detail, it is important to explain its provenance. It has emerged from an amalgamation of three core approaches to education policy and curriculum analysis, namely:

- Rizvi and Lingard’s, 2010 key questions for policy analysis (pp. 54–56)
- Hyatt’s policy analysis framework using critical discourse analysis (2013) and
- Winter’s deconstructive approach to curriculum *per se* and curriculum policy analysis (2006, 2011, 2014, 2018).

Fig. 1 The critical curriculum analysis framework.

²By the term “curriculum *per se*”, we refer to the materiality of the curriculum, for example, schemes of work, lesson plans, textbooks, teaching and assessment materials. These exist in textual, multi-modal or digital form. The process of translating curriculum policy into “curriculum *per se*” was described by Bernstein as “re-contextualization” (1990). Knowledge re-contextualization occurs through the pedagogic device, an analytical model to translate disciplinary knowledge into school knowledge (Singh, 2002, p. 572).

The first framework (Rizvi and Lingard, 2010) highlights policy origin, policy and textual issues and implementation, and policy outcome issues. These facets can all be applied to curriculum policy and curriculum *per se* analysis. The second (Hyatt, 2005, 2013) takes a semiotic route to investigate how authors of texts represent and thereby constitute the social world discursively, and the ideological power relations at work within and across these discourses. The final approach of Winter's work draws on a Derridean perspective aiming to disrupt and transgress the naturalized messages of curriculum policy and curriculum *per se* to open a space for something more socially just. The full framework can be found in Appendix 1, pp. 45–47. We acknowledge that the framework is incomplete in at least one significant aspect—that of curriculum enactment, in other words, the “diverse and complex ways in which sets of education policies are ‘made sense of’, mediated and struggled over, and sometimes ignored ... in schools”. Curriculum enactment involves “creative processes of interpretation and recontextualization” (Ball et al., 2012, p. 3), and we hope to extend the framework to encompass enactment, in collaboration with practitioners in the future.

In the section to follow, in order to demonstrate the potential of the framework, we use it to analyze a case study curriculum, the contemporary Geography General Certificate in Secondary Education (GCSE) in England.³ This analysis is necessarily limited in scope owing to the word restriction of the article, but its focus also demonstrates that the responsibility for selection of appropriate sections relies on the purpose and positionality of the analyst. For example, in the analysis to follow, a selection of sections of the CCAF was made for the analysis because of word restriction. In Fig. 1 (p. 38), the Curriculum policy deconstruction section, 2.1 Policy Archeology and 3.0 Curriculum *per se* structure were considered to be of lesser importance than other sections for the article and so were excluded from the analysis.

Applying the CCAF to a curriculum policy text ensemble: case study—geography GCSE in England

Introduction to the case study

The GCSE curriculum is usually taught to students aged 14–16 in English schools, during the educational phase known as Key Stage 4. While Geography (and History) are optional subjects for students at this stage, there is pressure on teachers to increase student recruitment to at least one of these subjects in order to comply with a performance indicator known as the E-Bacc or English Baccalaureate, which serves as one measure of quality of annual performance of schools. GCSE subject knowledge content is prescribed by the Department for Education (DfE), and passed on to the regulatory body, Ofqual which sets out the regulatory conditions and requirements for examination boards (or awarding bodies). These examination boards construct the curriculum specifications which must comply with Ofqual's conditions and requirements. In turn, schools are required to follow examination board specifications in order to prepare their students to engage with the curriculum and the associated examination. In the section below, we show how a selection of parts of the CCAF can be used to analyze a curriculum policy and curriculum *per se* text.

Curriculum context (p. 45)

Curriculum ensemble

For the purpose of this exercise, one curriculum policy text and two texts from one GCSE textbook have been selected as the “ensemble” for analysis. The policy text is *Educational Excellence Everywhere* White Paper (DfE, 2016) (Text 1) and the textbook is *GCSE Geography AQA*, written by Ross et al. (2016) (Texts 2 & 3). These three texts have been selected because their discursive analysis neatly illustrates the politics driving the configuration of curriculum policy knowledge and its manifestation in teaching materials. A wider range of texts could have been selected, including an earlier White Paper (DfE, 2010); the DfE subject knowledge content (DfE, 2014a), Ofqual Conditions and Requirements (2015); the examination board specification, examination question papers; mark schemes and examiners' reports, but word limit precludes these.

In order to address the curriculum context section of the framework below (1.2 *Curriculum drivers/warrants*, CCAF, p. 45), some research beyond the immediate documents under examination is necessary as will become evident.

Text 1 Educational Excellence Everywhere White Paper (DfE, 2016) https://assets.publishing.service.gov.uk/government/uploads/system/uploads/attachment_data/file/508447/Educational_Excellence_Everywhere.pdf.

Curriculum drivers/warrants

Origin of this curriculum

The contemporary Geography GCSE curriculum has multiple origins, including the establishment of the subject 2200 years ago (Bonnett, 2008, p. 4) and its historical role in the establishment of the British Empire (Livingstone, 1992; Winter, 2022). The

³The secondary school Geography curriculum was chosen as the focus because of the research interests of one of the authors, a former Geography teacher who researches in this area.

contemporary configuration of school Geography in England links back to earlier curricula, for example, the first Geography National Curriculum in England (Department of Education and Science, 1991) which was described as a resurgence of “back to basics” neo-conservative knowledge by Ball (1994). Since then, global economic success has become a priority for Governments and curriculum reform identified as a means of achieving it:

What really matters is how we’re doing compared with our international competitors. That is what will define our economic growth and our country’s future. The truth is, at the moment we are standing still whilst others race past.

DfE (2010, para 11).

While prioritizing school assessment demands introduced by international performance tests like PISA, the British Government, since 2010, has borrowed curriculum knowledge policy from the cultural literacy movement in the US, led by E.D. Hirsch, to re-institute traditional academic knowledge into the contemporary Geography curriculum at GCSE level (Winter, 2014).

Why was this curriculum adopted (drivers) & why was it adopted at that time?

As a backlash to the 1997–2010 Labor Government’s focus on a “learning-to-learn” or a skills-based approach to pedagogy and an integrated approach to subject knowledge, the Coalition Government argued for the return to a traditional academic approach to the curriculum, this time, supported by Young’s “powerful knowledge” discourse (2008).

Who were the “players” (groups, interests, individuals) involved in establishing the contemporary geography GCSE curriculum agenda?

A wide range of policy-makers and influencers have participated in the reconstitution of Geography in schools over the last 30 years. These include Government Ministers, such as the Secretary of State for Education, Michael Gove (2010–2014), DfE, Ofqual, Geography teacher education and Geography researchers, officials of examination boards and subject associations, freelance consultants, textbook writers and publishers.

How were the policy drivers (warrants, justifications) disseminated to teachers?

A range of mechanisms was used to disseminate the policy drivers to teachers, including White Papers, news media, Government speeches, teacher union newsletters and subject associations, as well as academic articles and social media. Some of these authors promoted the curriculum reform policy, some critiqued it.

Text 1 Educational Excellence Everywhere White Paper (DfE, 2016, Ch 6, paras 6.1–6.24, pp. 88–93) https://assets.publishing.service.gov.uk/government/uploads/system/uploads/attachment_data/file/508447/Educational_Excellence_Everywhere.pdf.

Curriculum policy deconstruction (p. 46)

Textual deconstruction

Section 2 of the CCAF, Curriculum Policy Deconstruction (2.2), will be used to guide this part of the analysis of the 2016 DfE White Paper (See **Appendix 1**, p. 46). The first question (2.2.1) in the CCAF is “How is this curriculum legitimated?”, in other words, what is its warrant, or the justification for its existence? Appeal to rationality is used in the policy document in the form of reference to outcomes, since the policy promotes certain outcomes with which it would be hard to disagree: “High expectations and a world-leading curriculum for all” (DfE, 2016, Ch 6, pp. 88–93), stating:

The best possible education for adult life in 21st century Britain is one that equips children and young people with the knowledge, skills, values, character traits and experiences that will help them to navigate a rapidly changing world with confidence (6.1).

Other accountability warrants are made throughout the policy document, for example, “world leading assessments and qualifications”, making these “as challenging as those in the highest performing countries around the world” (6.15), valorizing global competition, international benchmarks and performance tables.

Responses to the CCAF question (2.2.2, p. 46) “In what ways does the curriculum draw on discourses from outside education?” are found in the 2016 curriculum policy text (Interdiscursivity). The discourse of colonial celebration is promoted as the aspiration against a background of falling educational standards. This appears in the form of the good future story vs. the bad past story, or Legitimation via Mythopoesis. Evidence is found in the reference to knowledge about “the best which has been thought and said” (Arnold, 1869, p. 5), from a quotation by Matthew Arnold, a 19th century poet, cultural commentator and school inspector, who supported the cultural canon as the preferred guide to social development. The text also refers to a British-centered curriculum which

“balance(es) three Shakespeare plays and the study of a broad sweep of British history” (6.6), as well as “the development of the character traits and fundamental British Values that will help children succeed ... ” (6.1, e).

The second example of interdiscursivity occurs in the interpenetration of discourses of science and education in the policy document. Cognitive Science is “new” (“has shed fresh light”), is “ambitious” and “maximise(s) pupil understanding and minimize(s) confusion, giving teachers professional autonomy over how to teach” (6.6). Evocative evaluation is evaluation which on the surface appears ideationally neutral but which evokes a positive or negative reading (Martin, 2000). The text resonates with such evoked evaluation, with many references to “academic rigor”, “robustness”, and “a new gold standard”. The word “rigor” occurs six times. Likewise, discourses of modernity and entrepreneurialism occur. Both are presented as self-evidently “good”, for example, “a 21st century education that equips them [students] with the knowledge and character necessary for success in modern Britain”, (Inset box, p. 88), and “These new qualifications will command the confidence of students, employers, and further and higher education institutions” (6.22).

Text 1 Educational Excellence Everywhere White Paper (DfE, 2016, Ch 6, paras 6.1–6.24, pp. 88–93).

https://assets.publishing.service.gov.uk/government/uploads/system/uploads/attachment_data/file/508447/Educational_Excellence_Everywhere.pdf.

Curriculum knowledge

The third section of the analysis focuses on the questions in Part 4 of the CCAF, *Curriculum knowledge* (Appendix 1, p. 47). The recurrence of the word “knowledge” (21 times) in the curriculum policy indicates that it forms a key underpinning concept (CCAF 4.1.2), and the knowledge promoted here is described as “a core body of knowledge” which is “set out” in a certain “format”, stating it is presented in a particular pre-determined way. References to: “the best that has been thought and written”; “the sort of knowledge-based, ambitious, academically rigorous education which every child should experience” and to the English Baccalaureate⁴ (EBacc) signal this “core body of knowledge” to be traditional academic knowledge. This statement is confirmed by the repetition, as noted above, of adjectives which serve as accountability warrants in the promotion of the curriculum, such as “robust”, “rigorous”, “ambitious”, “academically demanding”, “challenging”. All these characteristics allude to the notion of “powerful knowledge”, discussed in the context section of the article (p. 37). Participation in the competitive global education community is referenced: “national assessments and qualifications ... that ... are as challenging as those in the highest performing countries around the world” (6.15, p. 91). Two other key concepts (CCAF 4.1.2, p. 47) appear several times in this extract. The first is the equal opportunities discourse, evidenced in the statement:

We want every child, wherever they live and whatever their background or needs, to receive a 21st century education that equips them with the knowledge and character necessary for success in modern Britain.

Inset box, p. 88.

The second is the conceptualization of learning as “knowledge acquisition”, knowledge accumulation (“new knowledge is acquired through situating it within existing knowledge” and “the more a child knows the more they are capable of learning” (6.4, p. 89)). In summary, five key discourses have been identified in the curriculum policy extract: the knowledge-based curriculum, a core body of knowledge, the promotion of “quality” knowledge of a certain kind, equal opportunities/entitlement and a transmission/acquisition conception of learning. All, one, or a selection of these discourses can be analyzed to a deeper level in line with the four points of problematization contained within the CCAF 4.1.4: [i] underpinning assumptions, [ii] standpoint; [iii] responses and [iv] implications.

Text 2: Ross et al. (2016, p. 203) “Colonialism” Curriculum knowledge.

In this section, we present a critical analysis of the second text using the CCAF. The following paragraph about colonialism was published in a Geography GCSE textbook (Ross et al., 2016), currently used in schools under the heading of “Historical causes” [of uneven global development]:

... By the end of the 19th century much of Africa and parts of South America and Asia had been divided up between the European superpowers. Countries such as the UK, Germany, Spain and France had powerful empires and colonies. Since 1950 former European colonies have gained independence. In many cases this has been a difficult process, resulting in civil wars and political struggles for power. Money has been spent on armaments and some governments have been corrupt. This political instability has held back development.

Ross et al. (2016, p. 203).

⁴The EBacc is not an award or a qualification, but an accountability indicator which contributes to the assessment of performance by schools in terms of their ranking in performance tables, making it a high-stakes indicator. When first introduced, it consisted of a percentage of students achieving high GCSE grades in five traditional academic subjects. This later increased to eight subjects in 2013.

We focus on the CCAF questions found in 4.1, p. 47. The key discourse is colonialism (4.1.2) and the kind of knowledge (4.1.1) represented here fits the category of out-dated, inaccurate, evasive disciplinary knowledge, since it is telling “half a story” as Olusoga states (cited in Akbar, 2016). The history of colonialism is not only over-simplified in the paragraph (4.1.3), but is grossly and offensively mis-represented, raising the question “why?” Stuart Hall reminds us of:

... the profound historical forgetfulness—what I want to call the loss of historical memory, a kind of historical amnesia, a decisive mental repression—which has overtaken the British people about race and Empire since the 1950s. Paradoxically, it seems to me, the native, homegrown variety of racism begins with this attempt to wipe out and efface every trace of the colonial and imperial past.

Hall (1978, p. 26).

The assumption underpinning the paragraph is that following independence, former European colonies were unable to govern themselves and became violent, corrupt and politically unstable. In other words, the knowledge informing these assumptions is imperialist, colonial knowledge—driven by an assumption that colonial rule was a “good thing”. This represents the “single story” standpoint of colonialism (Adiche, 2009), told from the perspective of those holding colonial power, since the voices of the less powerful, the colonized, are silenced. The role of Europeans in colonial genocide, violence, dispossession, slavery and exploitation is missing, erased. Questions of who benefits and who loses out are relevant here, as the paragraph indicates that the reputation of the European powers remains intact, while calling into disrepute the moral character of those living in former colonial countries. This reductive binary of “coloniser = ‘good’/colonized = ‘bad’” indicates further deployment of evoked evaluation. This echoes through the curriculum in the form of the depiction of “High Income Countries” (HICs) as superior to “Low Income Countries” (LICs), highlighting the “West is Best” discourse. At the same time an implicit racialization is at work in the paragraph as well as in the curriculum overall, but never explicitly stated, that people racialized as white predominate in HICs and people racialized as black in LICs.

In relation to opportunities for inquiry into and critique of this paragraph by students, and gaining an understanding of student/teacher responses to it (4.1.4, [iii], p. 47), we need to examine this and other curriculum texts deployed in the classroom more closely and comprehensively, and conduct classroom studies to investigate the reactions and emotions that these discourses may generate among students and teachers. But, at the same time, it is important to acknowledge the authority and power of the textbook, and the over-crowded curriculum in a high-stakes assessment regime such as GCSE, which, combined, constrain the amount of inquiry and critique teachers can facilitate in English schools (Winter, under review). The fourth section, (4.1.4 [iv]) of the CCAF poses questions about the effect of such discourses about colonialism in terms of educational equality, student subjectivity and citizenship. Again, recourse to further research is needed, but the following questions may be considered: how do students and teachers racialized as black and those with heritages in former colonial countries feel? How do students and teachers racialized as white feel?

In the third and final text discussed in this article, the CCAF is applied to a textbook image associated with a popular concept found in school geography, the Demographic Transition Model (DTM). The analysis here follows Teo and Zhu (2018) approach which aims “to better understand and interpret how meaning is constructed and construed through the co-deployment of linguistic and visual semiotic resources”. This concept of the DTM is not currently a compulsory part of Department for Education Subject Content for Geography (2014) but does form an important part of the examination board specification (AQA, 2016), which teachers are expected to follow.

Text 3: Textbook image—multimodal analysis.

In geography, the Demographic Transition Model (DTM), “shows changes over time in the population of a country” according to the textbook under examination (Ross et al., 2016, p. 198). The DTM shows how, as a country moves in an assumedly linear path from “traditional” to “developed” state, its population characteristics change in stages in terms of birth and death rates as it “progresses” from stage to stage. According to the graph on the preceding page to the image below, countries in stage one of the model have high birth rates and high death rates (“traditional rain-forest tribes” in Indonesia, Brazil and Malaysia) and those in stage 5, the final stage, have very low birth and death rates (examples given are Italy, Germany, eastern European countries and Japan).

The following image is taken from the textbook, p. 199. It shows “Countries at different stages of development”. Questions in the CCAF, section 4, Curriculum Knowledge (p. 47) are drawn on in the analysis of this image.

Countries at different stages of development

Stage 1: Traditional rainforest tribes

In parts of Indonesia, Brazil and Malaysia, small groups of people live separately with little contact with the outside world. They have high birth and death rates (photo **B**).

B Rainforest tribe

Stage 2: Afghanistan

Afghanistan is one of the poorest and least developed countries in the world. Its birth rate is 38 per 1000 and its death rate is 14 per 1000. About 80 per cent of the population are farmers who often need children to support them in the fields and tending livestock.

Stage 3: Nigeria

Nigeria is a newly-emerging economy (NEE) experiencing economic growth. The death rate is much lower than birth rate (see page 220). The country's population is growing rapidly.

C Germany's ageing population

Stage 5: Germany

Germany is a well-developed country experiencing population decline as death rate exceeds birth rate. The birth rate is 9.5 per 1000, one of the lowest in the world. Women often have careers and few children. With an ageing population, Germany's death rate (11.2 per 1000) will continue to rise (photo **C**).

Stage 4: USA

The USA is one of the most developed countries in the world. Good-quality health care means death rates are low (8 per 1000). Women tend to have small families, choosing to study and follow careers. Therefore, birth rate is low (12 per 1000). Population growth is due mainly to immigration.

ACTIVITIES

- 1 Draw a sketch to show the DTM. Indicate on your sketch the links with economic development.
- 2 How does a falling birth rate reflect increased economic development?
- 3 How can an increasing death rate reflect high levels of development?
- 4 Consider the possible impacts for Germany of being in Stage 5 of the DTM. How might it have a negative effect on development?

Stretch yourself

Investigate the population and developmental characteristics of Afghanistan. How far do you agree that it is in Stage 2 with a low level of development?

Practice question

Explain how the demographic transition model is linked to economic development. (6 marks)

The kind of knowledge promoted in this image is traditional academic knowledge (4.1.1). The DTM is a long-established model used in the geography education community to teach about population change and global development. According to the textbook, the model is based on “changes that took place in Western countries such as the UK” (Ross et al., 2016, p. 198). While this is true in general terms, the model was conceived and developed in the USA (Szreter, 1993), where it was used in the weaponisation of population control in global anti-communist policy. In terms of simplification (4.1.3), three points stand out: the model focuses on birth and death rates only, ignoring migration as a factor of population change; the model’s complex political provenance is erased, and it alludes to the Malthusian idea of “disease, famine and war” as maintaining a steady population level in traditional societies, without critique. The DTM provides a Western population change process as a bench-mark which is used, unproblematically, to compare, categorize and “other” non-Western countries.

The perspectives of those without power, in other words, of those people living in non-Western countries, are not evident in the textbook discourse of the DTM (4.1.4 [ii]). The model promotes an unashamedly Western viewpoint. The binary at work here is the contrast between the “traditional” and the “developed”, with the authority of the assumedly universal application of the model left unquestioned. A close examination of the images reveals the construction of racialized difference and differential value in terms of level of “civilization” ascribed to social groups. This point is relevant to the CCAF question of promotion of equality (4.1.4 [iv]). The “stage 1” image (“Traditional rainforest tribes”) shows a family group, wearing traditional clothing which exposes bare skin, sitting in a relaxed way, on the floor outdoors in the rain forest, implying “primitive” surroundings. In contrast, the German senior citizen sits, fully clothed, upright on an IKEA-type chair, indoors. A degree of exoticization of the “rainforest tribe” is evident when contrasted with the image of the white European norm of the German woman, and the textual reference to the “tribes” isolation from “the outside world” reinforces this negative idea of the “tribes” being “left behind”. Indeed, this point recurs in the graph on p. 198, which indicates that the UK was at stage 1 (the stage of the “traditional tribes” in 2016) in the DTM pre-1760. The text attached to each image suggests the negativity of high natural population increase in “tribal” societies compared with the positivity of high natural population decrease in “civilized” societies.

In relation to the CCAF sections 4.1.4 [iii] “responses” and [iv] “implications” of this image, (p. 47), no opportunities are provided in the textbook for student critical reflection on the DTM or the image under scrutiny, and the nature of affective responses from students and teachers can only be imagined. The DTM discourse and image do not conjure a sense of equality between different social groups, but instead indicate the construction of difference, similar to that described by Willinski (1999), in his account of how dominant educational discourses serve to “divide the world”. The implicit message carried by the texts about relative superiority and inferiority and racialization may be engaged with by students and teachers or discarded as “business as usual”, or may create alienation and stigmatization for those racialized as black or having family heritage in Indonesia, Brazil and Malaysia. A third possibility is that students and teachers challenge the othering produced by the textbook—a response which represents an action of critical and responsible citizenship.

Conclusion

As argued earlier, curriculum plays a crucial and central role in education. This is because it not only involves a certain selection of knowledge, but also because the language of curriculum carries political power to constitute certain meanings and thereby influence the reader in certain ways. This is the case in both curriculum policy and in curriculum texts of all kinds. Curriculum is a political phenomenon. It exerts power by both propagating and obstructing, discursively, the configuration and circulation of “truths” (Foucault, 1972, p. 49). Since curriculum is such a powerful political phenomenon, critical analysis is necessary to excavate its political drivers, and to understand its ideological goals. This is particularly salient in an era of increasing control through educational neo-liberalization and securitization around the world. Several examples can be found in England. First, the National Curriculum reform (DfE, 2014b) increased the volume of prescribed knowledge content in the English school curriculum, stifling the creativity and professional autonomy of teachers as critical intellectuals, subject specialists and pedagogues, positioning them effectively as educational technicians. Second, recent policies require teachers to teach a “Fundamental British Values” curriculum, the origin of which lies in a counter-terrorism strategy (HM Government, 2011) which coerces teachers to operate as state security agents (Winter et al., 2021). Third, Relationships, Sex and Health curriculum policy (DfE, 2020) states that schools should not use materials produced by organizations that take “extreme political stances”, including “a publicly stated desire to abolish or overthrow democracy, capitalism ...”. In effect, this amounts to state censorship of sections of British school History, Sociology and Politics curricula (Busby, 2020). Fourth, the powerful knowledge movement, by canonizing core knowledge that represents “... respect for the best that has been thought and written” (Gove, 2012),⁵ restricts student and teacher accessibility to the full range of potential knowledge, authorizes certain prescribed configurations of knowledge as superior to others, while obscuring the provenance of that knowledge deemed to be powerful.

Each of these curriculum policies above constitute meanings in certain ways for students and teachers. At the same time, the underpinning high-stakes accountability regime holds curriculum compliance firmly in place, allowing little room for challenge and change. Teacher autonomy has been eroded under technologies of performance which Ball et al. describe as “deliverology”

⁵This quote is adapted from Matthew Arnold (1869) book *Culture and Anarchy*. The actual quote is “... the best which has been thought and said in the world” (Preface, p. 5).

aimed to turn students and teachers into “economically useful citizens” (2012, p. 139). The problem, however, extends beyond students, teachers and the school curriculum. According to Carr (1998), a dialectical relationship exists between the kind of curriculum we create and the kind of society in which we wish to live. Society creates the curriculum and the curriculum prepares students for life as citizens in society. If the goal of the education system is a pluralistic democratic society, then a pluralistic democratic curriculum is needed: democracy and curriculum “stand in a reciprocal relationship such that each provides the foundations on which the other is erected” (p. 337). The creation of a pluralistic democracy requires a curriculum in which reflective enquiry, critical intelligence, collective deliberation, collaborative social relations and the habit of resolving difficult practical, moral, political and social problems is exercised (See Carr, p. 336). An intelligent pluralistic democracy cannot be born out of a curriculum driven by coercion, competition, nationalism and political censorship. The Critical Curriculum Analysis Framework offers one approach by which students and educators might unravel and transgress the complex political discourses of curriculum policy and curriculum *per se* to construct a curriculum fit for an intelligent pluralistic democracy. Just as curriculum is a complex, dynamic and evolving phenomenon, so is this article.

Christine Winter acknowledges funding provided by The British Academy/Journal of Moral Education Trust and thanks are extended to Stephanie Borg, Gareth Bramley, Louise Kay, Georgina Spencer and Daniel Whittall for their constructive comments on an earlier draft.

Appendix 1

The critical curriculum analysis framework CCAF.

1 Curriculum context

1.1 Curriculum ensemble

1.1.1 What documents/texts make up the curriculum ensemble? Why were these documents/texts selected?

1.2 Curriculum drivers/warrants

1.2.1 Where did this curriculum originate, including consideration of any relevant global factors/institutions? Does it have links to earlier curricula?

1.2.2 Why was this curriculum adopted (drivers) & why was it adopted at that time?

1.2.3 Who were the “players” (institutions, groups, interests, individuals) involved in establishing the curriculum agenda?

1.2.4 How were the policy drivers (warrants, justifications) disseminated to teachers? Were the drivers hidden or explicit?

2 Curriculum policy deconstruction

2.1 Policy Archeology

- 2.1.1 What discourses frame the curriculum policy text? Are these globalized discourses?
- 2.1.2 What evidence is there here of interdiscursivity?
- 2.1.3 To which “problem” is the curriculum policy constructed as a solution?
- 2.1.4 How is the curriculum policy problem conceptualized? Will the curriculum policy as constructed “solve” the problem to which it is a response?
- 2.1.5 What alternative curriculum policy problem constructions have been rejected/neglected/not articulated, or actively considered & rejected or ignored?
- 2.1.6 How have the curriculum policy players constructed its context and/or history?
- 2.1.7 What complementary curriculum policies (i.e., policy levers, the mechanics of policy implementation, e.g., inspection, funding, metrics) were put in place to support the achievement of curriculum goals?
- 2.1.8 Does the curriculum policy contain vagueness and ambiguity? Is there recourse to “personal responsibility” in liberal values mode, with the purpose of avoiding official accountability?

2.2 Textual deconstruction

- 2.2.1 How is the curriculum legitimated? By an appeal to authority (legislation, etc. “we must do this”); by an appeal to rationality (“it’s the only sensible thing to do”); by an appeal to morality (“it’s the right thing to do”) or through narratives of potential success/failure if the policy is or isn’t enacted.
- 2.2.2 In what ways does the curriculum draw on discourses from outside education (economics, science, religion, etc.)? In what ways does the curriculum draw on other texts (citation, referencing, quoting, statistics, paraphrasing, etc.)? What are the impacts/implications of these discursive/textual borrowings?
- 2.2.3 How does the language used construct assertions as positive or negative? How overt/explicit or covert/implicit are these constructions?
- 2.2.4 What presupposition exist in the curriculum and how are they realized via the language?
- 2.2.5 What lexical and grammatical features of the curriculum construe certain readings of the text in certain ways—this may be applied to each of the categories above as they are all realized in language.
- 2.2.6 What do any images/tables/figures included in the curriculum imply/evoke in terms of the information imparted?

3 Curriculum *per se* structure

Teaching texts: curriculum specifications, textbook pages, test/examination questions, worksheets, teaching artifacts, online teaching materials, etc.

3.1 Curriculum construct-ors/-ion

- 3.1.1 Is the curriculum constructed from top-down (by curriculum experts, Governments) or bottom-up (by students, teachers, communities) or both or by another approach?
- 3.1.2 How was the curriculum introduced: quickly, with adequate teacher consultation, training and resources; in negotiation with teachers, students and communities?
- 3.1.3 Have research and curriculum precedents been used in support/justification/production of the curriculum? How credible is this evidence?
- 3.1.4 What is the relationship between the content of the official curriculum requirements and the teaching texts? What curriculum features stand out as different in the official curriculum text and teaching texts (“translation/recontextualization”)? What are the implications of these differences?

3.2 Curriculum structure

- 3.2.1 Is a technical (objectives/outcomes led) curriculum structure promoted?
- 3.2.2 What is the relationship between the curriculum structure (including knowledge), pedagogy and assessment?
- 3.2.3 How will the outcomes be measured/assessed/evaluated? What does this imply—exams might imply this is to be learned by rote and not engaged with critically?
- 3.2.4 Is the curriculum targeted toward a specific group of learners, e.g., “giftedness”/“learning disability”/“less able” or is it inclusive? What are the arguments supporting the targeting of curriculum to specific groups of learners?
- 3.2.5 Is the curriculum part of a high-stakes assessment regime?

4 Curriculum knowledge

4.1 Curriculum knowledge epistemology/ontology

- 4.1.1 What kind of knowledge is promoted in the curriculum—disciplinary (traditional academic subject knowledge; knowledge “what?”) or competency (skill-based knowledge; knowledge “how?”), vocational knowledge or a mix or something different?
- 4.1.2 What key concepts/ideas/discourses recur through the curriculum?
- 4.1.3 Are key concepts/ideas/discourses over-simplified? What elements of the concept/idea/discourse are over-simplified? Why?
- 4.1.4 For a selection of key concepts/ideas/discourses:
- [i] Underpinning assumptions:
 - What assumptions underpin the key concepts/ideas/discourses? (politics, ethics, values)
 - What knowledge informs them?—out-dated theory? Business theory? Public consciousness? Recent rigorous research evidence? What are the academic arguments and evidence in favor and against?
 - [ii] Standpoint:
 - Is the “single story” represented? Or is the concept/idea/discourse viewed from different perspectives ie those with power; those without power?
 - Whose viewpoint is being promoted?
 - What is missing from the key concepts/ideas/discourses? (historico-political background (e.g., colonialism); a global dimension; power relations; counter-arguments and narratives)?
 - Are binaries evident in the curriculum? What purpose do they serve? Do they operate masquerade/veneer to imply value-freeness/a-politicalness?
 - Are universal truths promoted? What purpose do they serve?
 - What curriculum knowledge is missing and why?
 - Who/what benefits and who loses out when the concept/idea/discourse is applied?
 - [iii] Responses:
 - Are teachers and students encouraged to be critically reflective about their own stances and lived experiences relating to the concepts/ideas/discourses?
 - Are concepts/ideas/discourses open to inquiry by students and teachers?
 - Are concepts/ideas/discourses presented in such a way to engender a feel-good response from dominant groups who engage with them? (What does the discourse make students and teachers feel?)
 - [iv] Implications:
 - Do the concepts/ideas/discourses promote equality?
 - What are the implications of the concepts/ideas/discourses for constituting student & teacher subjectivity?
 - What kind of citizen do the concepts/ideas/discourses promote?
 - Are there opportunities for students to create their own curriculum knowledge?

21st century skill in the curriculum

Due to technological developments, societies all around the world are rapidly changing with major implications for the ways we live, work and learn. Several scholars acknowledge the impact of these changes on the nature and types of jobs (e.g., [Levy and Murnane, 2006](#); [Van Laar et al., 2019](#)). Others emphasize the increasing importance of ideas and knowledge as the new commodity in a technology-driven society (e.g., [Anderson, 2008](#)). Further, the need for a normative re-orientation on human values such as privacy and equity is called for (e.g., [Duff, 2008](#); [Baeva et al., 2021](#)), because of technological developments such as machine learning and the use of algorithms ([Webb et al., 2020](#)). These developments require a reconsideration of the competences people need to be able to actively contribute to a technology-driven society (cf. [Ananiadou and Claro, 2009](#); [Gordon et al., 2009](#)). Therefore, a key curriculum issue in many countries nowadays is what the implications of these changes are for what needs to be taught and learned in schools.

The call for 21st century skills in the curriculum is a manifestation of the concerns diverse stakeholders in society have about the current relevance of the formal education curriculum in times of rapid changes in society. Curriculum can be defined as design for learning ([Van den Akker and Nieveen, 2021](#)) and includes decisions about objectives, content and organization of what is worth teaching and learning ([Walker, 2003](#)). Taking decisions about what is worth teaching and learning in the 21st century is not simple. It is always the outcome of a social-political process, in which views on the purposes of the curriculum in society are discussed among stakeholders and turned into concrete goals and content for teaching and learning. Part of this process is to find consensus about three key functions of education in society: qualification, socialization and personal development (or subjectivation in terms of Biesta) ([Biesta, 2013](#)). Qualification refers to the knowledge, skills and understanding we need to equip students with in order to prepare them for contributing to society in their later life. Socialization is the preparation of students to internalize a society's culture, including its norms and values. Finally, through the curriculum, education aims to contribute to the personal development of each individual learner.

The curriculum as design for learning ([Van den Akker and Nieveen, 2021](#)) becomes tangible in the form of curriculum artifacts (materials, programs), which are prepared for use at different educational levels. The most well known levels are the macro level (the curriculum of a jurisdiction, usually a nation, a state or province), the meso level (the curriculum of a school, a school board or a district) and the micro level (the classroom curriculum). Because of globalization and an increased need for lifelong learning two levels have been added recently: the supra level (curriculum frameworks proposed by supranational organizations such as UNESCO, the OECD and the European Union) and the nano level to be able to pay attention to individual learners (the curriculum to personalize learning) ([Van den Akker, 2003](#)). It is important to realize that these five curriculum levels do not form a hierarchy, but interact with each other. Curriculum materials describe the intentions of what needs to be taught and learned in formal curriculum documents—the intended curriculum. But the curriculum also becomes manifest in two other representations: the implemented curriculum shows how the curriculum is implemented in the practice of teaching and learning in schools and classrooms. Finally, the attained curriculum reflects what students actually experience and learn ([Van den Akker, 2003](#)).

Conceptualizing 21st century skills

In many countries the discussion about what needs to be taught and learned in a technology-driven society started outside the educational arena. In the first decade of the 21st century supranational organizations and public-private partnerships fueled the discourse. The DeSeCo project (the Definition and Selection of Competencies) initiated by the Organization of Economic Cooperation and Development (OECD) was among the first projects that formulated lifelong learning competencies that were considered relevant in a technology-driven society (Rychen and Salganik, 2001). Similarly, the European Union formulated key competences (Gordon et al., 2009). Hard- and software companies were particularly active in public-private partnerships that aimed to formulate what 21st century skills imply for school curricula and how these skills can be implemented in the practice of teaching and learning. Examples of such partnerships were the Partnership for 21st century skills, which was mostly active in the US (Partnership for 21st Century Skills, 2009) and the Assessment and Teaching of 21st Century Skills (ACT21S), which operated at an international level (Binkley et al., 2012). More recently the OECD launched “The future of Education and Skills—Education 2030” project, which aims to update the lifelong learning competencies formulated in the DeSeCo project. This project places particular emphasis on the importance of individual and collective wellbeing as an important aspect of reconsidering the curriculum with a view to society in the future (OECD, 2018). These various initiatives resulted in concrete definitions and frameworks, which describe and justify the need for generic goals that are important for 21st century curriculum.

While in the US the term “21st century skills” is mostly used for addressing the goals that need attention in the 21st century curriculum, the term competency (e.g., lifelong learning competency and key competency) became more popular in Europe. Despite these different terms, there is consensus that the general features of these learning goals: (1) are generic and transversal, which means that they are relevant across many domains; (2) not only refer to skills, but also include knowledge and attitudes; and (3) are context-specific as they prepare learners to cope with complex problems with wicked tendencies (e.g., Gordon et al., 2009; Veltman et al., 2019). Klieme et al. (2008) use the term disposition instead of skill or competency to refer to the learning goals relevant in the 21st century. They define these as “context-specific cognitive dispositions that are acquired by learning and needed to successfully cope with certain situations or tasks in specific domains” (Klieme et al., 2008, p. 9). Their definition refers not only to cognitive components, but includes also behavioral, motivational, social and ethical, aspects. Because the term 21st century skills is internationally used, in this contribution we adhere to this term.

Despite consensus in the overall features of 21st century skills, the different frameworks use different language and different concepts to describe these skills. Voogt and Pareja Roblin (2012) analyzed eight frameworks (including the ones described above) leading to a set of skills that were considered core in almost all frameworks. These are: cooperation, communication, social and cultural skills, problem solving, critical thinking, digital literacy, creativity and self-regulation. From this list it is clear that most 21st century skills are by no means new. For instance, already in 1910 Dewey (1910) mentioned critical thinking as an important skill that education should pay attention to. And although digital literacy may seem new, it has been discussed as educational goal in many countries already in the 1990s (Plomp et al., 1996). While many of these skills are not new, the call for explicit attention to 21st century skills in the curriculum was, in part, a reaction to the narrow emphasis on basic skills and high stakes testing in many countries (Au, 2011; Bryderup et al., 2009), which left little room for the development of the generic skills that are needed to become flexible lifelong learners in a society that is rapidly changing.

It must be noted that the call for 21st century skills in formal education is also disputed. Hilt et al. (2019) argue that the call for 21st century skills takes a neo-liberalistic stance on education. Biesta (2013) further argues that an uncritical acceptance of 21st century skills in the curriculum represents a narrow view on the purposes of education. He warns that a focus on 21st century skills seems to emphasize the qualification (i.e., to prepare students for living and working in a technology-driven society) and the socialization functions of education (i.e., taken the technology-driven society for granted without a critical stance) at the cost of personal development. Probably as a response to the latter critique, in recent developments values and student well-being have become much more at the forefront of the discussion around the question of what needs to be learned in order to prepare students for a future society (OECD, 2018).

Position in the curriculum

Notwithstanding agreement on what can be understood by 21st century skills and why they are important, the position of these skills in the formal curriculum and their realization in curriculum practice is often the subject of debate. One of the reasons is that 21st century skills cannot easily be separated from each other and are often overlapping, which makes it difficult to formulate unambiguous learning goals and to assess them. Another reason is the fear that these skills become an extra add-on to the curriculum, which may result in curriculum overload. We briefly illustrate these points using two skills: critical thinking and digital literacy.

Critical thinking can be approached from three perspectives: the philosophical, the psychological and the critical pedagogical perspective. Central in the philosophical perspective is the formation of a reasonable and just judgment, whereas the psychological perspective emphasizes higher order thinking skills, and the critical pedagogical perspective mainly pays attention to effects of argumentation and reasoning in the social context (Volman and Ten Dam, 2015). To be able to formulate concrete learning goals, which can be taught and assessed it is important to provide a clear definition in which these three perspectives are incorporated. For this reason, and after a broad consultation with many experts, the American Psychological Association (APA) published a definition in

which critical thinking is seen as goal-oriented and the ability to give an independent judgment. They formulated six cognitive skills (interpretation, analysis, evaluation, inference, explanation and self-regulation) and nineteen dispositions (e.g., clarity, orderliness, reasonableness, persistence, trust, self-confidence, flexibility, open-mindedness, willingness to reconsider) that are required to develop critical thinking (Falcione, 1990). This broad definition of critical thinking clearly demonstrates that it is difficult to isolate critical thinking from other 21st century skills, such as for instance problem solving, creativity, social and cultural skills and communication. The definition of the APA suggests that critical thinking can be understood as a set of cognitive skills and dispositions that can be applied in various disciplines (Ennis, 2018). Although the definition was meant to give guidance to teaching and learning, it remains a challenge to incorporate this broad understanding of critical thinking in curriculum design. A prominent discussion about generic skills, such as critical thinking, is to what extent they are domain specific. Scholars such as Ennis (2018) argue that critical thinking as a generic skill enables transfer to various contexts, although research shows that this is not self-evident (Lazonder and Egberink, 2014). Ennis (2018) argues that some substantive knowledge is necessary but not crucial in teaching critical thinking skills. Others argue that domain knowledge is essential for being able to apply critical thinking skills (and comparable skills such as problem solving and creativity) at an in-depth level (McPeck, 1981). In this view, critical thinking skills should be given a domain-specific interpretation, as is the case, for example, with historical reasoning (Stoel et al., 2017), the teaching of science inquiry in primary school science (Kruit et al., 2018), the thinking of the architect (Hamel, 1990), or the clinical reasoning by doctors (Norman, 2005).

Digital literacy is not a simple technical ability but a complex skill based on the integration of (meta)cognitive and technological skills (Aesaert et al., 2014) and linked to motor, emotional and social skills. It is more than just operating digital technology. The aim is to be able to understand the impact of digital technology on life and work and to be able to use digital technology for various purposes that are relevant in society and for personal use, such as: problem solving, creating information, providing information/ accessing information, communication, cooperation and safe and responsible use of the internet. Current digital literacy frameworks and curricula mainly emphasize problem solving, information acquisition and processing, critical thinking and creative and innovative use of digital technology (Siddiq et al., 2016). A well-known framework is the European DigComp reference framework (Ferrari, 2013), which structures digital technology skills in five categories: information, communication, creation, safety and problem solving. These categories show overlap with other 21st century skills. Many countries worldwide have formulated policies for integrating digital literacy in the curriculum for compulsory education (Eickelmann, 2018; UNESCO, 2016) and have started the implementation process. In few countries digital literacy is a separate subject in the curriculum, such as England. However, in many countries the goals for digital literacy are integrated in traditional school subjects (e.g., Canada, BC, Germany NRW, Belgium, Australia) also because countries try to avoid extra add-ons to the curriculum, as this may result in feelings of curriculum overload of teachers. However, integration of digital literacy in other subjects requires teachers who are qualified to teach digital literacy and see the relevance for their subject (Voogt and Brummelhuis, 2014).

These opposite views, as illustrated by critical thinking skills and digital literacy, fuel the discourse on where to situate 21st century skills in the curriculum. Should these skills become integrated across subject domains, do they require a separate subject in the curriculum, or do they need to be taught in cross-curricular projects? The two examples show that two different types of considerations are at stake. At the one hand the answer to this question is guided by the discussion on the nature of the skills (i.e., whether they generic or domain-specific). On the other hand the answer to this question is also driven by concerns about curriculum expansion. Although it is generally acknowledged that the curriculum needs to respond to developments in society, expanding the curriculum with new content also implies less time for traditional content.

Macro level: 21st century skills in curriculum frameworks and standards

Countries all around the world have been responding to calls from society to renew curriculum frameworks and standards in primary and secondary education. The attention for 21st century skills has a prominent place in these calls. Yet, countries are at different stages in the curriculum renewal process and they differ significantly in the way they handle it (Voogt and Nieveen, 2017). While some countries are in the middle of the curriculum renewal process itself (e.g., The Netherlands, Wales), other countries have formulated frameworks, set new standards and are implementing the new frameworks and standards in schools (e.g., Singapore, New Zealand, Canada BC, Scotland). Some countries (e.g., England, Germany NRW) have renewed parts of their curriculum by, for instance, adding subjects or adapting standards for specific subjects (e.g., digital literacy), while other countries have chosen to review and renew the complete primary and secondary school curriculum. There are countries that periodically renew the curriculum, such as Finland and Norway, who do this every ten years (Pietarinen et al., 2017; Siveskind and Westbury, 2016). However, in many countries (e.g., The Netherlands, Ireland) curriculum renewal is an ad hoc process (e.g., FitzPatrick and O'Shea, 2013; Kuiper et al., 2013), often fueled by a shared feeling of urgency (Barber et al., 2010). The different approaches toward national or state curriculum reform affect the socio-political process of adoption of 21st century skills in the curriculum.

The curriculum renewal process usually starts with creating awareness, engaging stakeholders, identifying the needs for a new curriculum and a political decision to formally start the renewal process. For instance, the process in New Zealand started with an analysis of the social, economic and technological changes taking place in society, a discussion on the changing meaning of knowledge due to technological developments, and the observation that the learning sciences offer increasing understanding on how people learn. This analysis led to the argument that schools need to contribute to the development of competencies that enable students to contribute to the wicked problems of the 21st century (Sinnema, 2011). These discussions at the country level

are often fed by the supranational initiatives as described earlier. It is not always the governments who take the initiative to start the curriculum renewal process. In England the Royal Society started the discussion about the need for Computing in the curriculum (The Royal Society, 2012). In the Netherlands advisory councils to the government initiated the process of curriculum renewal with a discussion about the position of technology in society and the potential for learning (e.g., [Wetenschappelijke Raad voor het Regeringsbeleid, 2013](#)). Usually many different stakeholders are involved in the awareness process, from within the educational arena (e.g., teachers and teacher unions, school boards), the community (e.g., parents' associations) and the private sector (Law, 2014; Pietarinen et al., 2017). Technology is increasingly used to inform stakeholders about the content and process (e.g., Website; twitter), and to promote stakeholder engagement (e.g., discussion forums) (Nieveen et al., 2014). For a system-wide impact on school and classroom practices, it is important to have a shared vision about the needs for and affordances of 21st century skills in the curriculum as a starting point (Van den Akker and Nieveen, 2021). Such a shared vision provides a rationale for specific decisions that need to be made during the design and development of curriculum frameworks and standards for a 21st century curriculum.

21st century skills in school curricula

Although 21st century skills are often not yet systematically integrated in national and school curricula, schools and teachers are increasingly paying attention to these skills. Voogt and Pareja Roblin (2012) distinguished three ways of integrating 21st century skills in the school curriculum: as new subjects or new content in existing subject domains, as cross-curricular competences acquired in specific projects or through curriculum transformation. All three approaches are found in studies of schools that put efforts in the implementation of (a subset of) the 21st century skills in curriculum practice. Tan et al. (2017a) studied Singaporean schools that integrated some of the 21st century skills. They found examples of schools that implemented a subset of the skills in single subjects, such as math, science, arts and physical education. Also schools were found that implemented 21st century skills across the curriculum. For example a school that infused the arts throughout the school curriculum, and a school that emphasized globalization and practiced 21st century skills in an exchange with schools in the US. The 21st Century skills were also an important component of the educational concept of innovative school's in the Netherlands (Volman et al., 2020). This study investigated how self-regulation, collaboration and creativity were embedded in the curriculum. In schools that had just started to implement 21st century skills in their curriculum, the skills were seen as an add-on to the traditional curriculum. However, schools where 21st century skills were part of the school's mission for quite some time a learner-centered approach was adopted and project-based and inquiry learning was emphasized, indicating a cross curricular approach. This study showed that teaching 21st century skills in the curriculum positively correlated with students' perception that they mastered them. In an international case study of innovative pedagogical practices using technology from 28 countries, Voogt and Pelgrum (2005) found an emphasis on fostering 21st century skills through the use of technology. They observed three foci in the way technology was used: single subject, thematic and school-wide. In all three foci 21st century skills were addressed, but in a different manner. In all three foci students and teachers were positive about the innovative practices, but evidence on the impact of the 21st century skills on student outcomes were lacking. In the Single Subject Curricular Focus technology was used to teach traditional content at a deeper level, emphasizing problem solving and critical thinking skills. The innovative technology-based practices in the Thematic Curricular Focus explicitly aimed at developing 21st century skills, such as problem solving, digital literacy and collaboration. This was accomplished through cross curricular project-based or thematic learning activities that were organized in addition to a subject based curriculum. In the School-wide Curricular Focus the innovative technology-based practices were embedded throughout the school curriculum and were part of the school's mission. These schools had the view that students are responsible for their own learning, and emphasized self-regulation skills while also paying attention to the other 21st century skills. However, although (innovative) schools are actively integrating 21st century skills in their curriculum, the implementation in mainstream education is often challenging. In the next section we discuss some prominent issues that affect the implementation of 21st century skills.

Implementation in the curriculum: prominent issues

Assessment

Assessment requirements often steer the way the curriculum is being implemented. Several studies showed that lack of alignment between the intention to teach 21st century skills and assessment practices is a threat to the implementation of 21st century skills (e.g., Au, 2011; Sinnema, 2011; Tan et al., 2017b). To overcome this problem assessment practices need to be developed that allow the assessment of 21st century skills in an authentic context. Webb and Gibson (2015) argue that the affordances of technology makes it easier to assess 21st century skills, because with technology it becomes possible to embed the assessment of 21st century skills in authentic performance tasks. An example is the OECD PISA study of the assessment of collaborative problem solving skills (OECD, 2017). Building on the work of Hesse et al. (2015), who developed an assessment framework for assessing collaborative problem solving skills, the OECD PISA study developed a computerized environment in which students had to interact with virtual agents to solve problems. This approach has proven to be a valid and reliable way of assessing such skills (Stadler et al., 2020). Another example is the International Computer and Information Literacy Study (ICILS). In this study aspects of digital literacy are assessed in a computerized environment. Students have to complete both closed tasks (answering a question. Clicking a link) and authentic open tasks (e.g., creating an information product) (Fraillon et al., 2020).

Capacity building

The implementation of a curriculum that incorporates 21st century skills usually requires attention and time for capacity building at all levels of the school system (governance, leadership, teachers) (Desha et al., 2009). Leadership continuity is essential in the implementation of complex change in schools, such as the implementation of 21st century skills in teaching and learning. Leaders need to trust their teachers and provide a supportive school culture for the change (UNESCO, 2010). Teachers need to be qualified to teach 21st century skills and understand what is expected from them in order to prevent misunderstandings. For example, in New Zealand teachers had difficulty in seeing the relation between the new curriculum that contained standards about 21st century skills and subject-related standards. They needed support to think in-depth about the connections between the two parts of the standards and to prevent that they perceived 21st century skills as an add-on to the curriculum (Hipkins, 2016).

At the school and teacher level guiding materials can help to exemplify how the curriculum can be realized in school and classroom practice (McAra et al., 2013). Several studies show the importance of a middle layer, local or private agencies which act as a broker between the requirements set forward in national standards and the possibilities and constraints of the local context. Such agencies can help leadership and teachers in developing local interpretations of the curriculum (Toh et al., 2016; Pietarinen et al., 2019).

Time lag

While transformations in society are changing fast, the process of curriculum development is usually slow. It might take 10–15 years before we can see effects of attention for 21st century skills in society, as this is the period it usually takes from the start of the curriculum development process until students equipped with 21st century skills leave the school system (Desha et al., 2009). This implies that we need to prepare students now for a future that is unknown (Hilt et al., 2019). It is too simple to state that because 21st Century skills are generic skills we may expect that these skills are not only relevant today but also in the future. Changes in society often imply a need to review the rationale for teaching the skills as well as relevant content for teaching the skills. Moreover, skills such as digital literacy need constant adaptation because of technological developments. The need to update the lifelong learning competencies formulated by the OECD in 2005 and in 2018 is just an illustration of the uncertainties that are inherent to the development of a curriculum for the future.

Globalization and transnational curriculum	57
Internationalization of curriculum studies	59
Acknowledgment	62
References	62

It can be said that postcolonial thought is in many respects a globalized way of thinking, even if initially it does not use that term. In the first place, it shows that there is little disjunction between the history of the nation and that of the empire (...). Postcolonial thought demonstrates that colonialism itself was a global experience which contributed to the universalization of representations, techniques and institutions (in the case of the nation state, even of merchandise of the modern kind). It shows that this process of universalization, far from being a one-way street, was basically a paradox, fraught with all sorts of ambiguities.

Mbembe (2006, p. 5).

By opening this text with Mbembe's epigraph, I denounce some decisions that inhabit it. Besides offering me the option for a post-colonial and post-structural reading—possibly due to the geographic place where I was born, I live and work—this epigraph marks a willingness to get closer to the discussion of the curriculum field from the perspective of policy. However, this does not mean taking state curricular policies—at the interface between national and global demands—as the focus of this text, but understanding that the constitution of the field itself is an antagonistic struggle for hegemony (Laclau, 2011; Lopes and Macedo, 2014) as well as a performative action of normativity (Butler, 2015). There is also, in such a disposition, an ethical desire to question power operations that sustain “the relationship between the recognizable and the unrecognizable” (Butler, 2015, p. 5), thus implying a need to seek to understand the field production policies “from within [contingency and global incommensurability] and against it” (Bhabha, 1998, p. 21).

Terms such as globalization and transnational do not refer to new phenomena. Although such an interpretation is not consensual, as Mbembe (2006) and other post-colonial authors point out (Bhabha, 1998), these terms can even be associated to colonial experiences. Especially when dealing with this statement from the South American context, where colonialism refers to the navigation of the 16th century, there is possibly some temporal imprecision—which does not disturb post-colonial thinking in view of its distrust in relation to Modern temporal linearity. Without the pretension of origin, I take the second half of the last century as a time when globalization, defined by Mbembe (2006) as “the central phenomenon of our epoch” (p. 7), became an object of great value to sociological analyzes (Giddens, 1999; Castells, 2004; Bauman, 1998, 2005). I specifically refer to the post-war moment, when the integration of markets and also the search for major transnational agreements—for example, the Universal Declaration of Human Rights—were intensified. With the end of the Cold War and the large-scale growth of Internet use, the discussion of the global seems to have reached its peak in the late 1980s, to the point where Rosenberg (2005) calls it the *Zeitgeist* of the 1990s. The reiteration of the concept produced its displacement and terms such as transnational—also widely used—or globalization resurfaced in the arena. At times, they aimed to mark relevant theoretical distinctions in relation to globalization, at other times, to minimize the emphasis on the economic that this discussion had assumed.

I here do not aim to discuss such phenomena in their sociological and economic nuances, but only to address their intersections with the curriculum field over the past few decades. Such intention finds its first challenge in the proliferation of meanings for curriculum, recognized by authors with different theoretical views (Pinar, 2004; Young, 2013; Hopmann, 2015). When putting my post-structural option into operation, I deviate myself from an epistemological definition, and I assume that the field, at a given moment, is only the effect of the power relations that constitute it as a performative discourse (Butler, 2015). In this understanding, curriculum studies could not even be defined by an object that they seek to address—as in the question of authors as different as Pinar (2004) and Young (2013) about “what curricular theory is”. On the contrary, their answers [and even the question] sanction what is legitimate as a curriculum in the political game that constitutes the field as something heterogeneous and contingent. Without disdaining the failure with which all normativity lives (Butler, 2015), I operate here with the fiction that, named and summoned, goes by the name—which intends to give it identity—of curriculum studies. It is important to highlight that fictions matter because they have effects, including the sanctioning of what can be thought and said at a given moment about, in this case, the curriculum.

With this understanding of the field, the methodological path I have taken here has enabled me to seek meanings shared by researchers in “places” established in the political games that constitute it. I have done so in a non-exhaustive and less rigorous way, not because of sloppiness, but because I only aim, theoretically, to question some meanings that circulated and continue to circulate in these “places”. I thus have chosen to wander, like Poe (1993) when diving into the night of the city behind the man in the crowd, or follow Benjamin (2006) suggestion: to really know a city, it is necessary to get lost in it. So, I combed through, without quantitative pretensions, the two most cited journals explicitly dedicated to the curriculum theme—*Journal of Curriculum Studies* (JCS); and *Curriculum Inquiry* (CI)—to read texts that, in the last twenty years, dealt with phenomena such as globalization and trans/internationalization. The very decision to wander around the Global North reflects—and reproduces—the strength of the

researchers based there in the struggles for hegemonizing meanings for the internationalized field. I acknowledge the existence of extensive work on curriculum studies in different countries in Latin America, Africa and Asia, but I must confess that the little I know of its content came from what gained visibility in these (global?) “places” that I have studied via my sojourns through publications such as these two major curriculum studies journals.

Although both journals present themselves as international and as thus supporting the very idea that an academic field requires a certain sharing of traditions, it was curious that I felt myself in different places when exploring each one. Obviously, there is a circularity of meanings between the two, but there is also some untranslatability that cannot go unnoticed when discussing the inter/transnationalization of curriculum studies. Each journal has a different set of authors and, in many cases, the themes brought up for discussion or the emphases they assume differ as well. Most notably, possibly, the fact that the *JCS* favors a more sociological approach, with a greater presence of the analysis of the State’s role in global phenomena, while in *CI* non-national identities gain space.

Like [Calvino \(1990\)](#) traveling narrator, I here have invented two narratives that are even possible as means to escape tourist maps. My narratives are not about the most common themes in one or the other journal, nor will I bring only or predominantly what I read during my journal travels. I purposefully mixed these texts with other readings that constitute me as a researcher in the field to produce reflections on these narratives that I explore throughout the two sections into which this paper is divided.

The first of them has a dialog with Sociology, Economics and Political Science and takes concepts, such as nation-state, (neo) liberalism and globalization as important analytical tools. Thus, curriculum theory is considered in a close relationship with state curriculum policies and the narrative focuses on the impacts of global flows on curricula. I assume that globalization has broadened the reach of (neo)liberal normativity and I scrutinize the effects of that normativity on national and local curricular policies, especially due to the historical importance of curricula in the construction of a nation’s (sometimes unitary) metaphor. At the same time, I am concerned with the reduction that this movement has been producing in the sense of curriculum, what [Miller \(2014\)](#) called return “with a vengeance” (p. 18) of the “exclusively managerial and technical-rational orientations” (p. 18). However, I try to react to think of normativity in a saturating way, which, faithful to post-structural lessons, highlights its iterative or performative character.

In the second narrative that I compose, which was only implied through the two journals, I start from the movements that, in the last twenty years, have broadened the connection of researchers of the field at the international level, assuming that there is an effective desire to deal with difference and alterity. This is undeniable in the many initiatives coordinated by William Pinar and other researchers that culminated in the creation of the International Association for the Advancement of Curriculum Studies (IAACS) and its journal, *Transnational Curriculum Inquiry (TCI)*.¹ Thus, like the Association, the two versions of the *International Handbook of Curriculum Research* ([Pinar, 2003, 2014a](#)) and the project, “Curriculum Studies: Intellectual Histories, Present Circumstances” ([Pinar, 2010, 2011, 2014b, 2015](#)), aimed to expand the debate in the field beyond North America and Europe.

When I lost myself in both journals, I found the same desire in the movement for greater internationalization of editorial committees, but I also came across a strong concentration of authors and references in the Global North. I have no doubt that “as editors, [our colleagues] are committed to publishing articles that reflect diverse approaches to curriculum studies and a wide range of theoretical frameworks” ([Gaztambide-Fernández and Thiessen, 2012](#), p. 1). The homogeneity of text styles and research formats narrated in them, however, indicate that perhaps, as noted by the authors themselves, “the internationalization Project (...) runs the risk of perpetuating dynamics of colonization that have historically marked academic and educational enterprises” (p. 9). Thus, in a movement somewhat opposite to that of my first narrative, in the second, I seek to think about the challenges of producing an internationalization of the field that is not intended to be colonial, but that has to deal with asymmetric flows of power or with “traces of imperialism and colonialism (...) discernible [even in cosmopolitan projects]” ([Pinar, 2010](#), p. 2).

Globalization and transnational curriculum

[the] interest in policy (and in policy/practice relations) is itself a form of thinking about curriculum that is locating specific, arising from countries that have a history of formal state policy frameworks for curriculum, as distinct, for example, from the history of curriculum in the USA where strands of theorizing curriculum flourish (reconceptualists theorizing in particular) that have very little origin in or concern with “policy”.

[Yates \(2016, p. 367\).](#)

I start from Yates’ assertion that interest in policy is a way of thinking about curriculum; however, I disagree with the possibility of attributing geographic—and historical location—to that theorization. For the traveling narrator who toggles between *JCS* and *CI*, this was undoubtedly a tempting link. However, if it is true that the North American field, which is known, in great part, as one influenced by the reconceptualization and its proliferations that [Malewski \(2010\)](#) calls post-reconceptualization,² operates with other concerns, one could argue that the standards & testings binomial is the focus of much of the country’s curricular discussion.

¹In constituting this scene, I think it is important to highlight that I have been working within the Association since the mid-2000s, having participated in the projects carried out by it.

²I assume a broad reading of the movement—contesting the hegemony of the standards & testings model in Curriculum Studies—enclosing phenomenological and critical studies, as well as a whole set of post-structural approaches ([Malewski, 2010](#)).

This is explicit in different works, among which are the historical retrospective of the field carried out by Pinar et al. (1995) and the book, *Teaching by Numbers*, in which Taubman (2009) analyzes recent North American curriculum policies. Hopmann (2015) will even maintain that the North American curriculum movement at the turn of the 20th century, focused on “learning results [and] (...) toward the psychology of learning (...) was then exported during the 1960s into the continental European context (...) as a ‘better’ form of education planning” (p. 17). To the author, this has been repeated recently, for example, with the expansion of the Organization for Economic Co-operation and Development (OECD) governance over European curricula. Indeed, the organization itself (OECD, 2005) admits that the definition of competencies in its 2003 project is depository of the idea of generative skills or standards that comprised an American document from years before.

Still, in line with Yates’ (2016) argument, the scene I construct for my first reflection came to mind when browsing through the JCS texts and is, in some way, located in Europe. This is because it goes beyond the links between curriculum studies and state policies, referring to the impact of global flows on the non-uniform metaphor of national cohesion.³ I do not want to produce an origin for such a metaphor—in the European Enlightenment—nor to deny its spread across the Global South, for example as attested by the narratives gathered in the *International Handbook of Curriculum Research* (Pinar, 2014a). Even in the USA, where the idea of nation has its own nuances (Scott, 2007), there were several moments when curricula were called upon to play a relevant role in nation building (Kliebard, 1992; Pinar et al., 1995; Goodson, 2002; Franklin, 1986).

I begin my scene at some point in the second half of the last century when curriculum policies, sometimes with the adjective “national” included, began to make reference to transnational or global citizenship. It may be appropriate to consider that this movement took place in very different ways. On the one hand, the post-war world had begun to question totalizing discourses. The nation metaphor, described by Bauman (2005) as one of the most powerful mechanisms for creating the illusion of belonging via birth, was one of them. Identity, reason, subject—categories belonging to the same theoretical spectrum—were read with suspicion. While Cha-terjee (2000) denounced the nation’s bonds with authoritarianism and its disrespect for ethnicities and cultural differences, Bhabha argued that, as a fragile and unstable representation, the nation was unable to guarantee the promised unity. On the other hand, national states were also weakened by the creation of economic blocs, as well as by the expansion of neoliberal governance, which Brown described as “the peculiar form of reason that configures all aspects of existence in economic terms” (Brown, 2015, p. 17). Despite a certain antagonism between these two movements, that synchrony may have produced an atmosphere more conducive to the weakening of the nation state and national identities. It is not possible, however, to measure the cross-impact—in the sense of reinforcement, but also of opposition—between global governance and the disruptive potential of post-colonial criticism.

In the field of curriculum studies, this scenario raised proposals in defense of cosmopolitan, multicultural or global curricula, with biases ranging from liberal to critical, as well as with approaches focused on the environment, peace and citizenship (Heilman, 2010). In most of these proposals, the former links between curriculum and national identity are weakened, although universal curriculum visions are not necessarily called into question. Although I stumbled upon some of them on my journeys through the journals,⁴ especially through *CI*, my scene will not emphasize them. Instead, I center my attention on the effects of the rise of neoliberal normativity on national states, which shifted the focus “from a political to an economic semantic order” (Brown, 2015, p. 41), and on curricula national policies produced in the last twenty years. I am interested in highlighting the action of multi-lateral organizations such as the World Bank (BM), United Nations Educational, Scientific and Cultural Organization (UNESCO), OECD and Inter-American Development Bank (IDB), as well as of the networks that are replacing and strengthening them, in the governance of national policies. As Ball (in Avelar, 2016) points out,

in many countries, the framework, limits and possibilities of policy thinking are actually constrained, at least to some extent, by the language, assumptions and concepts which the World Bank and the OECD are articulating, advocating, promulgating, writing about, speaking about in conferences, and talking about with education ministries during visits and conferences. (p. 10)

In agreement with Ball, Sellar and Lingard (2013) argue that the expansion of global governance of curriculum policies intensified when the OECD mobilized its expertise in collecting and comparing statistical data for the creation of Program for International Student Assessment—PISA. Elsewhere, Lingard (2016) claims that, since then, the organization has disseminated, through well-structured propaganda, “a type of Weberian technical rationality as a demonstration of modernity of any nation” (Lingard, 2016, p. 618). To this end, it has been established soft governance exercised through the creation of infra-structural conditions, as well as through a “well-established capacity to shape the view of key actors in education across local, national and global scales” (Sellar and Lingard, 2013, p. 722).

With the expansion of the power of the OECD in the definition of global policies, agencies such as UNESCO, with a more cultural profile, lost space. Some of their concepts, such as competence, were appropriated receiving a more economic and instrumental guise. Since the 2000s, the OECD has redefined this concept, establishing what Mausethagen (2013) calls conceptual governance. The definition still used today, with huge impact on national curriculum policies, was created in mid-2000s: “a competency is more than just knowledge and skills, it involves the ability to meet complex demands, by drawing on and mobilizing psychosocial resources (including skills and attitudes) in a particular context” (OECD, 2005). Anderson-Levitt (2017) defends that this

³Papers about the pervasive effects of globalization on former curriculum policies in *CI* focus mostly on subjectivity or identity, as can be seen in Casella (2005) and Beltrán (2018). In *JCS*, although national identities play a big role, the focus on identity is not totally absent (LaSpina, 2003).

⁴Just to mention a few: Warriner (2017), Rizvi and Beech (2017), Hull and Stornaiuolo (2014), Pashby (2015), Jickling and Wals (2008), Saito (2010).

definition, broader than the previous ones and presented in less clearly economic terms, responded to the worsening of the international financial crisis, when the rhetoric of employability that competence would guarantee has eroded.

For Lingard (2016), among others, OECD governance via PISA has “legitimized a new educational agenda in favor of further school reforms” (Lingard, 2016, p. 622). Less than having its results used for decisions on national educational policies, PISA creates a “shared political enterprise” (Addey, 2016, p. 690) at the international level. The evaluation is used “for externalization purposes” (Lingard, 2016, p. 621), providing national governments with a rhetoric of modernity and external legitimation for their actions (Anderson-Levitt, 2017). By this means, the OECD governance constitutes “epistemic communities of policy analysts, bureaucrats and politicians within the Organization and in member countries” (Sellar and Lingard, 2013, p. 712).

Despite recognizing the importance of multilateral organizations, especially OECD, in formulating policy, Ball (Avelar, 2016) has stressed the need for attention to new social actors in the global education landscape. The author suggests the expansion of global governance networks to encompass networks exercised by “various philanthropic organizations and foundations” (p. 10), as well as by “edu-businesses and business foundations (...), social enterprises, charity global organizations, [and] (...) well established NGOs” (p. 10). Such decentralized “political communities” (Ball, 2012, p. 5) are organized around common problems and with a view to their solutions, producing “new forms of sociability” (Ball, 2012, p. 9). As with OECD governance, while antagonizing national states, global networks do not dispense with them as a sphere that will guarantee legitimacy for the solutions they promote. Expanding such governance, they create “new narratives about what counts as good policy” (Ball, 2012, p. 6), which put in place a new public management capable of producing solutions, but which mainly worked in defining the problems and its relevance. Ball and collaborators (Ball and Junemann, 2012; Avelar and Ball, 2019; Ball, 2016) have been producing countless mappings that have given visibility to an intricate set of relationships in those new forms of management that, after all, promote the same economic logic envisioned in OECD governance for the past two decades.

The movement for global curriculum policies generates theoretical demands for Curriculum Studies. On the one hand, technologies for curriculum design focused on the definition of standards and their testing are developed. Differently from what use to happen decades ago, most of these networks are nowadays creating their own epistemic communities in order to develop research in their own centers outside the Universities or, in some cases, in closed privately financed nuclei within the Universities themselves. If “developing curriculum” (Pinar et al., 1995) has strongly moved to the global networks, a community of researchers traditionally linked to the Universities, on the other hand, have been kept mobilized by the task of “understanding” it (Pinar et al., 1995). Thus, these new ways of producing national curriculum policies, as well as their content, gained prominence as a major research theme within curriculum studies.

In my wanderings through the journals, I indeed perceived that many articles dedicated themselves to the analysis of the impact of global governance on the field and on national policies. As Yates (2016) suggested, communities where the fiction of the national state was more strongly established were more concerned about that, although the meanings of “national” varied greatly. In JCS, for example, a whole issue number dedicated to the “phenomena such as globalization and transnational policy (...) explored from a national/local perspective” (Wahlström et al., 2018, p. 587) was released in 2008. One year later, another issue explored the links between citizenship and curriculum, focusing on the “the changes and challenges facing citizenship education policy and curricula by way of case studies from Europe and beyond” (Philipou et al., 2009, 291). The articles together show that even within Europe, there are major differences⁵: “supra-national citizenship and its relationship to national citizenship and other groups [are conceptualized] in differing ways” (p. 291). In an even more diverse perspective, Zhao (2020) explores the impact on China of ancient cultural values of “globalizing West-centric discourses and practices” (p. 109).

In exploring the national and local effects of global governance, these studies are foregrounding the performative character of neoliberal normativity. As Brown (2015) points out, such normativity exists only in action and, therefore, is not able to saturate everything around it. While focusing on the normative strength of neoliberal governance, these papers make explicit its “inconstant, differentiated, unsystematic, impure character” (p. 20). In some other papers, the proliferation of differences in the normalized environment is even more prominent. Anderson-Levitt (2018) has argued that, despite the undeniable convergence global policies have been producing, it is fallacious to believe in a stronger unified global curriculum than that produced by the Enlightenment. In a paper analyzing the potentiality of comparative ethnographic and case studies, the author argues that they “reveal a richer picture of national patterns (...) and how the organization and tone of classroom activities vary from country to country” (p. 357). This is the case, for example, in the study by Wahlström (2018) in Swedish schools, in which the author “explores how education policy (...) is both enabled and constrained by transnational policy flows and national policy built up by social, cultural, historical traditions are enacted through curriculum at the classroom level” (p. 655). Among others, those papers point out to the always-possible popping-up of difference, no matter how asphyxiating normativity seems to be.

Internationalization of curriculum studies

... consciousness of the world arises from the actualization of what was already possible in me, achieved through my encounter with the lives of others, my responsibility towards the lives of others and towards seemingly distant worlds and, above all, towards people with whom I have apparently no connection: the intruders.

Mbembe (2006, p. 5).

⁵Ireland (Keating, 2009); Germany and Spain (Engel and Orloff, 2009); Cyprus (Philipou, 2009); Slovakia and Estonia (Michaels and Stevick, 2009); UK (Marshall, 2009).

As I explained, in this second narrative I make a movement somewhat opposite to the previous one, in which I highlight the political-associative and academic articulation of constituting an internationalized field in the curriculum. Inverse, because, as highlighted, among others, by Pinar (2010, 2014a), Carson (2009) and Gough (2000, 2004), this articulation responded to the acceleration of global rationality based on standards & testing: “internationalization can provide scholars with critical and intellectual distance (...) from those standardizing processes of globalization” (Pinar, 2010, p. 1). Also inverse because such an answer pointed to an explicit and conscious commitment to difference, as stated in the IAACS constitution, in which the association is described as being “established to support a worldwide—but not uniform—field of curriculum studies (...) [and] to provide support for scholarly conversations within and across national and regional borders about the content, context, and process of education, the organizational and intellectual center of which is the curriculum”. This commitment has echoed, in different ways, since the creation of the Association: in debate by CI (Carson, 2009; Gaztambide-Fernández and Thiessen, 2002), in papers in the JCS (Gough, 2000; Kim, 2010) and in the TCI (Gough, 2004; Miller, 2006), among others:

... the internationalization incurs an ongoing ethical engagement with alterity, resulting in the reconstruction of one's own self-understanding and social relation.

Pinar (2014a, p. 525).

... the more significant challenge for the internationalization of curriculum studies is one of understanding, of finding our place and forging new directions in these global circumstances that face education.

Carson (2009, p. 157).

... the “internationalization” of curriculum studies might then be understood not so much in terms of translating local representations of curriculum into a universalized discourse but, rather, as a process of creating transnational spaces in which local knowledge traditions in curriculum inquiry can be performed together.

Gough (2000, p. 339).

... in considering possibilities of transnational and transcultural collective exchange within the contexts of a worldwide curriculum studies field inflected by flows and mobilities, such “unknowingness” [at the core of what we know] might enable those of us attempting to create a worldwide field to avoid a scenario wherein the non-Western “other” is positioned to desire recognition only through assimilation or nativism, for example

Miller (2006, p. 36).

The difficulties that the internationalization of an academic field presents to those who launch themselves with a commitment and real desire to do so without controlling the proliferation of difference—as expressed in Miller's warning—are spotted by most of the scholars involved in the process. Gaztambide-Fernández and Thiessen (2002), for example, foreground that “curriculum scholars committed to internationalization (...) must remain skeptical of the impetus and the practice of ‘internationalization’ without a critical stance toward colonialism” (p. 10). While Pinar (2010), after remembering that colonialism is not absent from projects committed to alterity, argues that it is necessary to “continuing caution in (...) analytic efforts, an anxiety that any analysis risked neocolonial appropriation” (p. 2) in order to “engage in international conversation cognizant of world history and present injustices but not fated to reenact them” (p. 2).

The difficulties of the internationalization experience require that it is “further theorized and enacted by [in Miller's suggestion] considering differing points of view on transnational flows and mobilities of people, ideas, and communication and their effects on our abilities to engage in collective exchanges” (Miller, 2006, p. 34). Here, in a way, I want to launch myself into this task, in line with what was proposed by Miller,⁶ suggesting that internationalization, thought beyond the framework of national communities, has the potential to trouble the universal normative voice. It would not be a question of rearticulating national fields, but of perceiving them as the “resistance of the singular as a stain on the universal” (Hidleston, 2010, p. 296). In this perspective, the inter/transnational would appear in its complexity and could only be conceptualized as a retroactive effect of its own process.

To explore this argument, I expanded my wanderings through the *International Handbooks of Curriculum Research* (Pinar, 2003, 2014a), as well as through the 5 vol of the project, “Curriculum Studies: Intellectual Histories, Present Circumstances” (Pinar, 2010, 2011, 2014b, 2015). Even though both are thought from the distinctive perspective of the national—as “the nation (...) remains the imaginary and material site in which much of humanity experiences daily civic life” (Pinar, 2010, p. 2)—the sense of national operates in different ways in each of them. The handbooks bring together narratives from the curriculum field in 28 countries in the first edition (Pinar, 2003) and 34 in the second (Pinar, 2014a), which together make up the volumes as international handbooks. They are, therefore, somewhat marked by the national perspective that I want to avoid. The books in the curriculum studies project are collections of texts by authors from the same country, in which they “provide an intellectual history, an

⁶The author proposes that the post-foundational autobiographical inquiry can be the way “to activate, situate and/or interrogate conceptions, memories, fantasies, idealizations, or normalizations” (p. 45).

account of the present circumstances, and an overview of curriculum studies in [the specific country]. They also bring in their own research agendas" (Hawkins & Jacob as cited in Pinar, 2011, p. xi). I bring this project as a powerful example for thinking the national "as a stain on the universal", as suggested by Hiddleston.

It is not that, within the national narratives of the handbooks, it is not possible to perceive a strong transnational flow of authors and theorizations. On the contrary, they show that the field has always been internationalized, at least for those outside the great centers of production of universalisms. In many narratives, especially produced in the Global South, references to North American curriculum studies—Tylerian rationality, Schwab's diagnosis of the field, Reconceptualization, among other milestones in the history of the field in the USA—are constant. Other national histories also show a more regionalized influence potential, being shared, as a reference, by researchers from neighboring countries. In general, external interference in the constitution of national fields is tensioned by the authors of the texts, in readings with different levels of criticality, which does not prevent the sharing of these speeches from sanctioning meanings for the curriculum. Although in my travels through *TCI* and *CI*, I have come across few texts outside the Europe-North America axis, it was also possible to see the influence of certain national narratives on the naturalization of what is meant by curriculum.

In the case of handbooks, due to their nature of reference, the performative action of certain speeches on national fields is more evident, as general overviews of the field are presented in different countries. Although the stories are local, the narrated object is sanctioned as a curriculum by a universal normativity that is alien to them.⁷ With this analysis, I do not want to take away from the exercise-of-making-known-to-other-local-stories the potential, which it certainly has, of displacing the normative meanings of curriculum. I do not deny the reiterative or performative potential of normativity, but I suggest the need for a more obviously anti-colonial attitude. I am concerned that the distinctive experience of the other is put in place of that on which a non-distinctive curriculum theory is going to be produced. This opens, in my view, a colonial vision that is difficult to overcome, inscribed in what Bhabha (1998) calls the logic of diversity.

The theoretical-practical task proposed by the post-colonial landscape to overcome such logic is expressed in Butler's defense (2015) of "a critical approach to the norms of recognition, [which] can... begin to dismantle those more vicious forms of logic that uphold forms of racism and anthropocentrism" (p. 37). This is not an easy task for any field. It demands negotiating [or living] with alterity, risking the very recognition that is established according to the rules that are being challenged. Perhaps that is why Miller (2006) appeal, "trust me" (p. 44), when she says something that should be obvious: "there is no collective 'we' in the field of curriculum studies" (p. 44). After all, the "collective we" sanctions an acknowledgment, which, if displaced, can dismiss and/or put anyone in the position of the other. Even with this risk, the critical approach proposed by Butler (2015) needs to be taken because it is the responsible [and impossible] response that must be given to the other (Derrida, 2003).

I thus start from Miller's warning—that there is alterity in the [North-American] curriculum field and that it is not always perceived—to defend that the internationalization experience can help in the critical task proposed by Butler, in producing "the radical affirmation of the density of proximity, of displacement, even of dislocation" (Mbembe, 2006, p. 5). The innumerable examples of homogenization that globalization has been providing, some of which I explored in the previous section, perhaps disallowed such a statement, although it was also explicit there that there is no total saturation. At the same time, if there is no "collective we" in the North-American field, this displacement that Mbembe talks about does not depend on blurring national borders. Even if this is true, it is also important to note that the most prevalent "collective we" in Western Modernity is, possibly, national identities. By erasing them, post-colonial thinking, transnational in nature, advanced in demands out of respect for difference. For this reason, I advocate the power of the shock produced by trans/international contact also in the field of Curriculum Studies.

I use the 5 vol⁸ of the "Curriculum Studies" project as an expression of a powerful experience of internationalization of curriculum studies. With slightly different structures, all volumes include, in addition to the texts of scholars from the countries in focus and a brief presentation by their authors⁹, synoptic articles of the stages of the project that involved more intense exchanges among researchers from different traditions—national, disciplinary, theoretical, among others. I take these exchanges as the core of the project and as moments of productive—and iterative—shocks among traditions:

... the exchanges between panel members and participating (...) scholars occurred via the Internet over a (...) [certain] period. (...) [The] two rounds of questions and replies (...) [they were studied by Pinar] for their discursive movements, including the concepts those movements conveyed. (...) Participants [were invited] to critique [the] commentary, the first time in draft form (...) and the second time publicly in the epilogue, a "final word" articulated by the participants themselves.

Pinar (2011,¹⁰ p. 4–5).

Exchanges between panel members and participants—as well as Pinar's commentaries on the fields in the countries in focus, which are read in conjunction with the epilogues—offer glimpses of the difficulties and potentials of the internationalization of curriculum studies. In the articles, as in the texts of the handbooks, there are strong international influences in the constitution

⁷Interestingly, this apparent agreement on what the curriculum "is" divides space with analyzes that indicate strong hybridity in the field, which, to some, even leads to a certain lack of characterization.

⁸In a way, my experiences as one of those who participated as authors in the volume on Brazil as well as a member of the panel of experts in the South Africa stage of the project are also present in my presumptions throughout this article.

⁹Produced by Pinar from interviews/questionnaires focusing on the authors' biographies and their perceptions of the field.

¹⁰Text taken from the volume about Brazil, describing the process that occurred throughout the project.

of national fields, with abundant reference to the international literature on curriculum, as well as on related areas. In one of the volumes, Pinar (2011) goes so far as to claim that scholars “grapple with local legacies and present situations through concepts imported from Europe as well as from North America and elsewhere in South America” (p. 1). The exchanges, however, indicate that the colonial normativity that produced the sharing of universalized meanings of curriculum was being dislocated—with greater or lesser intensity—in its use. In some passages, there are even heated debates, since different statements were not always acceptable to those who saw themselves as owners of the displaced stories. In one disagreement here, in another there, some panel members let out feelings of possession of the universalized knowledge produced in the Global North or that there would be more correct or updated appropriations of the canon. As Pinar (2014b) points out, in the volume on China, “difference may always exceed our capacities to understand it, but ethical engagement with alterity requires not only the suspension of one’s assumptions—to the extent possible; it is a subjectively demanding undertaking—but active listening to whatever others (...) write and say” (n.p.).

At the end of each volume, Pinar produces syntheses (which in one of the volumes he classifies as synergistic), in which he intends to identify “concepts around which ‘discursive movements’ were organized”, highlighting that they circulate and “craft an unmistakable sense of shared difference” (Pinar, 2011, p. 198). Despite the attention to the difference, they seek to produce a “distinctiveness” (p. 198) of the fields in the countries, in a suture that is, in its own way, colonial, regardless of who produced it. Again, in the epilogues, however, the difference breaks out in recognition of another self—“what my local vision saw in those texts was a path of differentiation, and what internationalization presented to me was a displacement of approximation” (Macedo, 2011, p. 225). Or even, as a disagreement to be seen by the foreign and synoptic gaze: “I question the coherence of enunciation with my experimentations with images and words (...) I propose to work with the concept of fabulation” (Amorim, 2011, p. 219).

There are many other moments of disturbances created by exchanges among the scholars working in the project, some made explicit, others certainly silent. I do not intend to romanticize the experiences of internationalization that I brought as example—exchanges like these happen all the time, not dependent on international projects. My argument has been that spaces like these help the movement toward a wider recognition of the “others”. To sustain such an argument, it is necessary to make explicit that I do not assume internationalization and its institutionalization in IAACS, for example, as inclusive projects from the Global North. Rather, I posit these as necessary responses to the challenges and demands of a specific historical time. They are radical echoes of shifts in totalizing notions and have emerged in every arena as unexpected effects of the global norm, as local movements exploding around the world can exemplify. Thus, they are not magical places, but rather are being “regulated by norms of recognition that are themselves hierarchical and exclusionary” (Butler, 2015, p. 38). At the same time, with Butler, I assume that while “avowing and showing certain forms of interdependency, [they] stand a chance of transforming the field of appearance itself” (p. 43). Changings in the field of appearance are crucial to trouble the marginalizations produced by exclusionary experiences of recognition. And they are being made by those persons who, suddenly, appear through the always-there breaches. In that sense, from a USA perspective, it can make sense to bring together internationalization and reconceptualization (Pinar, 2014a), as the desire to open up exclusionary norms also animated the latter.

In this sense, I am treating “the experience of internationalization”—like so many others in which we are urged to live in difference—as an ethical imperative. It is as if the strangeness, to which the contact with otherness gives place, would put everyone in an eccentric position from where the fantasies of identity could be more radically displaced. It is not that the other who insists on appearing, displacing the identity metaphors—“the collective we”—will not disappear in a new recognition. It is precisely in this aporetic ambivalence between refusing and wanting—after all, we want to be “we”—that the ethical obligation to respond to the interpellation of the other lies (Derrida, 2003). When the unrecognizable other—the foreigner, in the sense of Derrida (2003)—insinuates himself/herself, we are placed in front of such an obligation.

It is common sense that globalization has been expanding regulation, producing a normativity from which, at times, it seems there is no way out—an interpretation that I, myself, enunciated in the previous section. Perhaps it could be potent to think of it as a kind of backlash, a response to the proliferation of others who do not fit in the fields of the appearance of colonial modernity. Perhaps, as proposed by Bhabha (2013), this globalization in which we are living is only “a transition space captured between a past that refuses to die and a future that will not wait to be born, a place deeply marked by the ambivalences of barbaric transmission” (p. 60). If so, the collectives that populate the field of curriculum studies are likely to be more and more transformed in order to expand the “we”.

Prelude

When I was invited to write a chapter for this volume, *Approaches to Curriculum and its Politics*, to be included in Elsevier’s fourth edition of the *International Encyclopedia of Education*, a temporary title was even suggested for my to-do chapter, i.e., Curriculum and globalization: Cultural, historical, and philosophical foundations of international curriculum. Reading that title, I was quite moved by the editors’ considerateness as these terms are what appeared on my personal website as “expedient” descriptors for my research interests. “Expedient” in the sense that there is indeed no single accepted sub-field of curriculum studies that is called “cultural, historical, and philosophical foundations of international curriculum”. Rather, I list them as boundary-setting descriptors of three broad domains, albeit hardly separable from each other and better put as “cultural-historical-philosophical”, to describe roughly what I have been exploring in international curriculum studies. I have now added “re-turning to” to the suggested title to foreground the fact that these three dimensions are not newly created ones in curriculum studies, but rather have been often marginalized or overwritten over the past few decades when curriculum and educational studies have always accented the, not less important though, political, social, and organizational entanglements along a neoliberal commodification logic. This being said, I put together this chapter as an overview of how I have come to delve into these entangled dimensions of international curriculum studies, say, what kind of curriculum scholarship and whose scholarship have guided me in my own learning and research trajectory. Henceforth, this chapter is in a sense an autobiographical summary of my recent research, far from a comprehensive review of the important works in international curriculum studies.

Curriculum studies and globalization & my entry points

Curriculum studies has always been a contested field since its very initial stage. According to Pinar (2008), the field has witnessed a four-stage evolution since early 1900s: (a) the Tylerian instrumentalization of curriculum development, (b) the reconceptualization movement of curriculum as a running course (*currere*) advocated by Pinar and his colleagues; (c) the multi-directional expansion of curriculum studies along the lines of narrative studies and phenomenological, historical, cultural, and philosophical foundations research; and (d) the post-2000 internationalization of curriculum studies. Pinar has undoubtedly made unparalleled contributions to internationalizing curriculum studies beyond the US boundaries, editing by himself or with colleagues a series of international or nation-based books on curriculum studies (say, on United States, Mexico, Brazil, South Africa, India, and China). Other similar efforts include, among others, international curriculum books edited by Wang and Eppert (2007), Baker (2009), Roofe and Bezzina (2018), Ashwani (2019), Hébert et al. (2019), and Ryan et al. (2020).

In the 50th anniversary issue of *Journal of Curriculum Studies*, Deng (2018) argues that Pinar’s and his colleagues’ reconceptualization, and the ensuing multi-dimensional expansion, movement of curriculum studies are in many ways a response to Joseph Schwab’s critique of the 1960s curriculum field as “moribund” and his call for inventing “new principles” and “new methods” in the field. These two movements, as a multi-discursive academic effort, have gradually and successfully replaced traditional curriculum studies focused upon curriculum development along a Tyler Rationale with a paradigm shift, namely, re-understanding

[☆]This project is partially supported by the startup grant from the Hangzhou Normal University, China.

curriculum from, among others, an array of historical, political, racial, (auto)biographical, aesthetical, theological, phenomenological, institutional and international, postmodern, and post-structural lens. This paradigm shift expands curriculum to an all-inclusive learning experience entangled with knotty issues of politics, gender, subjectivity, and stretches curriculum theorizing/studies to a broader scope intricated with new cultural, historical, philosophical, theoretical, and methodological perspectives. This multi-discursive academic effort was pushed further since the 21st century as a “postreconceptualizing” movement that intersects with posthumanism, queer theory, critical postqualitative studies and so forth, finally turning the curriculum field to encompass literally any topic related to politics, culture, society, environment, technology and human existence. To [Deng \(2018\)](#), the curriculum field has somewhat been transformed into a kind of “postmodern cultural studies” that is all-inclusive but neglects its core subject – practice and the inner work of schooling as a complex institution as its basic concern.

While Pinar’s and Deng’s comprehensive literature review retrospectively clarifies the apparently mixed field of curriculum studies in its dynamic, multidimensional, and rhizomatic growth and expansion, I would like to story-tell how my own research interests have grown along a transdisciplinary, transnational, and transcultural trajectory and ended up situating itself as a “re-turning to” the historical-cultural-philosophical foundations in international curriculum studies. Not particularly (or merely) inspired by the reconceptualization movement spearheaded by Pinar and other colleagues or the post-reconceptualization expansion in the Western scholarship, my research interests in curriculum studies were initially grounded in a different intellectual background of sociolinguistics and critical discourse studies along van Dijk’s and Norman Fairclough’s scholarship. I learned critical discourse studies through my former colleagues at Zhejiang University, [Shi-xu \(2005, 2016\)](#) and [Zongjie Wu \(2011, 2014\)](#), who have respectively worked very closely with van Dijk and Fairclough and endeavored to explicate a cultural and de-colonial discourse analysis paradigm that could help to explicate Chinese discourses as they are, not bogged down to the modern Western discourses and frameworks. In other words, my initial intellectual training was intimately intertwined with the issue of globalization (specifically the globalization of Western discourses) and (de)colonization, unpacking how globalizing discourses marginalize the Chinese cultural forms of knowledge (epistemes) in the guise of modernization and globalization.

Retrospectively speaking, my initial intellectual training provided two significant signposts or placeholders in developing my research interests in curriculum studies: a discourse/language lens and a transnational/transcultural framework. The discourse/language lens has been largely neglected in curriculum research except a few scholars like [Dwayne Huebner \(1966/1999\)](#) and [Daniel Tröhler \(2013\)](#). However, it smoothed my intellectual transition or expansion from a linguistic discourse analysis to a Foucauldian discourse critique of the issues of representation and signification, which in turn worked as a detour strategy and alerted me to the Chinese language as not a non-representational or a-representational language to the English phonetics but rather a disparate language system and being. Put differently, Foucauldian critique to modern Western language as a representational system not only moved me further to understand Heidegger’s ontological interpretation of language but also a historical mode of inquiry. [Heidegger \(1966/1996\)](#) vociferates, “thinking itself can be transformed only by a thinking which has the same origin and calling”. Inspired, I turned ‘discourse’ back to ‘language’ as a critical lens in my curriculum research and came to explore the Chinese language as an ontological being, an epistemic expression and trace of Chinese cultural mode of thinking or thesis, even though my former mentors commonly argue that modern Chinese language terms have been totally Westernized such that it is no longer a visible medium for traditional educational thinking and practice (see, [Wu, 2014](#)). One example is that I have discerned a Chinese “wind-education” discourse/language that expresses Confucius’ educational vision which I will unpack in detail in the next section.

This language lens has been continuously complicated by my exploration of transnational and global knowledge transfer and (re)production in relation to the issue of (de)colonialism and (de)coloniality, building off [Chakrabarty’s \(2000\)](#) well-known invocation: Western terms and frameworks are indispensable yet inadequate in explicating non-Western sensibilities. Pushing it further, I ask how it is possible to first discern non-Western sensibilities at this globalized modern world (as we researchers are already habituated to a modern Western and globalized representational epistemology) and then to portray them as they are and in the English wor(l)d, not through the English presentational framework. [Joao Parakseva’s \(2016, 2018\)](#) work on curriculum epistemicide helped me better link my own research interests with the (de)colonial scholarship that tackles the issues of modernity, coloniality, knowledge, being, and power. Specifically, as a form of colonialism, epistemicide “is constitutive of, rather than derivative from, modernity” ([Andreotti, 2011](#), p. 383), and “coloniality”, as the memory or legacy of colonialism, defines culture, labor, intersubjective relation, and knowledge production well beyond the limits of colonialism and long after the end of a colonial administration ([Maldonado-Torres, 2007](#)). This cohort of de-colonial scholars still ask the political critical question, say, *what/whose knowledge gets taught at schools as legitimate knowledge and what/whose not* (see, [Apple, 2000](#)), but they crossover the schooling boundary to the nation-state level. Furthermore, they alert us to another equally significant and yet often neglected question in mainstream Western scholarship, namely, *what other forms of knowledge exist(ed) in the world outside the Western epistemological harbor*. This question, as they rightly argue, is highly crucial toward reaching a de-colonial “cognitive justice” worldwide (see, [Sousa Santos, 2007](#); [Paraskeva, 2016, 2018](#)).

Intriguingly, these scholars also advocate language as a de-colonial gesture in such endeavor, perfectly abridging my two signposts of language and globalization in curriculum research. This resonates well with my own research on, through, and with language and discourse and sharpens my argument that language is both a colonial and de-colonial tool and expression. By that it means language can become a window for us to historically decolonize the Western modernity coloniality in transnational knowledge transfer and (re)production. It is not an investigation of the language system, but rather, to turn language as a window to glimpse into the cultural-historical-philosophical foundations of international curriculum studies. Such

a linguistic-cultural-historical-philosophical lens, as I show through my own research projects as below, revisions the otherwise rhizomatic yet ahistorical “ideal” linking and hybridization of culturally distinct onto-epistemologies, worldviews, languages, spatiotemporalities, and styles of reasoning. Instead, it explicates Other forms of knowledge outside of the bracket of the English wor(l)d, providing not an “alternative thinking of curriculum”, but rather, an “alternative thinking of alternatives” (see, [Sousa Santos, 2007](#)).

This being said, I detail out below my “re-turning to” trajectory in exploring the historical-cultural-philosophical foundations in curriculum research through a discourse/language and transnational framework. While taking up an autobiographical review of my own research projects, it also speaks volume to a broader curriculum scholarship that contextualizes, conditions, as well as transforms my own running course of learning and unlearning.

“Language/discourse” as a (de)colonial lens to disentangle the cultural-historical-philosophical foundations of international curriculum studies

“Language” and “discourse” are two popular yet contested notions. Linguistics and sociolinguistics usually view language as a self-justified linguistic system and discourses as specific language terms in use. Western philosophy and literary studies closely link language with the grounding issues of metaphysics, signification, and representation. With Michel Foucault and other post-modern or post-structural thinkers, language and discourse are no longer treated merely as a given linguistic system or term impregnated with fixed semantic meanings, but become a theoretical construct, an embodiment of historical-cultural styles of reasoning, which orders our thinking about social-political reality and truth. Unpacking language/discourse this way is to render visible the broader landscape of thought and practice. For example, Tröhler’s *Languages of Education* (2013) provides an original narrative on how the rooted religious languages of Protestantism and republicanism, in confrontation or negotiation, have historically, ideologically, and politically structured the schooling in Germany, US, and Swiss. Focused on contextualized religious and political languages (*langues*) rather than arguments (*paroles*), Tröhler’s book conducts a transnational archeology of educational arguments in a historical, analytical, and comparative way, adding new insights to Whig and Marxist interpretations. Similarly, [Horlacher \(2016\)](#) historicizes the German notion of *Bildung* as an educational language/discourse and explores how this notion gets deployed in other linguistic and cultural contexts, say, the Scandinavian countries and the English-speaking world, to impart varied educational aspirations and styles of reasoning. [Blumenfeld-Jones \(2016\)](#) pinpoints that the Protestant discourse/language derived from the Hellenic and subsequently Christian thinking has structured and ordered the Western world, marginalizing and excluding a Judaic rabbinic interpretive paradigm. All of them foregrounds language as an epistemic trace of historical and cultural style of reasoning, i.e., a language-episteme conjuncture.

Back in the 1960s, Dwayne Huebner, “the most important scholar in the field of curriculum studies” ([Pinar, 1999](#)), already alerted us to this language-episteme conjuncture when he vociferated that curriculum research was in search of a new language. To him, curriculum scholars back then were often overly dependent on scientific thought patterns (say, Tyler Rationale), which unfortunately blinded them to many other significant and important intellectual, say, religious and spiritual, traditions of both East and the West. Drawing upon Heidegger’s language thinking, Huebner envisioned five sets of languages and value systems, *technical, political, scientific, esthetic, and ethical*, that comes with a rich, wholistic, and meaningful curriculum. However, a curriculum delimited to the Tylerian managerial and instrumental language would only accent the *technical* value system, with ends or objectives carefully and accurately specified in behavior terms and activities designed to fulfill the ends. While such curriculum also attends to the *political* and *scientific* valuing, they often completely ignored the *esthetic* and *ethical* valuing, failing to account for the symbolic meaning of education as well as the very human-human encountering in educational engagements. Huebner’s critique remains true with today’s educational and curriculum practices that are still largely enthralled by a predominant learning logic, an instrumental trope, and managerial governance. Again, language represents an epistemic style of reasoning (see, [Zhao, 2021](#)).

[Michel Foucault \(1973\)](#) understands “episteme” as some historical “epistemological unconsciousness” that grounds and configures knowledge formation and its discourses within an historical era. Simply put, what language terms we choose to use and how we use them are closely entwined with our epistemic, conscious or unconscious, styles of reasoning. In this light, Huebner advises us to examine how people talk about or describe educational activities, to pay attention to the language they use, and to explicate the values or epistemic styles of reasoning intended through the used language. Only after such scrutiny can we produce a systemic rationality to maximize each of the five languages-values toward developing a wholistic curriculum and more meaningful educational activities. For example, drawing upon religious and spiritual wisdom and languages like “spirit”, “spiritual”, and “transcendental”, [Huebner \(1985/1999\)](#) intends to encompass the riches of education beyond the parameters of the Tyler Rationale. Furthermore, he (1966/1999) artfully rephrases the word “responsibility” into “response-ability” as a sought-after educational agenda. Namely, education is to cultivate students’ “response-in-the-world” (p. 112), a responsive sensitivity as well as sensibility with which students are awakened to, and become responsive to, the unveiling of the unconditioned, the new, and the unique in the real world.

Placed in the field of trans/inter-national curriculum knowledge (re)production, Tröhler’s and Huebner’s curriculum language research has implications for the issue of epistemic colonialism that has been constitutive of the modernization process of non-Western nation states and of modernity as coloniality (see, [Zhao, in press](#)). Specifically, the globalization of the Tyler Rationale language and other Eurocentric discourses not merely reduces curriculum and educational thinking into

an instrumental and managerial enclosure. More importantly, it marginalizes and overwrites other historical-cultural forms of knowledge or epistemes, both within and outside of the West, causing an effect of “curriculum epistemicide” (Paraskeva, 2016). It is to be noted here that linguistic epistemicide doesn’t merely mean a replacement of discourses per se. Rather, it is a killing of a mode of reasoning and a form of knowledge-making that come with different cultural discourse and language. In alignment with [wa Thiong’s \(1986\)](#) claims that language is the most important vehicle in subjugating the spiritual mindset of the colonized, [Paraskeva \(2016\)](#) foregrounds “linguistic genocide” as the “very core of the colonial and the neocolonial project” (p. 202). That is, “the production and reproduction of hegemonic forms of knowledge are precisely the institutionalizations of a linguistic or cultural epistemicide” (p. 241). Furthermore, these scholars argue that language can be flipped aside as a de-colonial tool in exposing and suspending the “darker side” of the Western modernity-coloniality of knowledge, power, and being toward global “cognitive justice”, a de-colonial gesture that hopes to bring to the foreground “a silenced and different genealogy of thought” ([Paraskeva, 2016](#), p. 80).

Over the past 10 years and with a Heideggerian-Foucauldian language-discourse perspective, I have been problematizing both the modernization of the Chinese language and the popularization of West-centric discourses in China as an imprint of modernity-coloniality (see, [Zhao, 2019a, 2019b, 2020a, 2021, in press](#)). However, compared with Paraskeva’s and others’ arguments, I have reiterated that things are a bit different with China and the Chinese language: Even though China was partly colonized from mid-19th to early 20th century, the modern Chinese language was not colonized or replaced by English and Chinese people still speak Chinese language. Nevertheless, the meaning making rationale behind the Chinese language is indeed Westernized-modernized into a conceptual signifier-signified mode of signification (see, [Zhao, 2019a, 2019b](#)). That is, the Chinese words are not dead, but the way they are read has been transformed to the extent that the original cultural-historical senses nurtured within each Chinese character has been overwritten by its modernized Western terms. Such modernization of the Chinese language happens as an effect of modernity coloniality since most Chinese academics and policy makers since the 20th century have critiqued the Chinese language as being illogical and welcomed a replacement by the modern Western terms (see, [Zhao, 2019b](#)). Put differently, the Chinese intellectuals and institutions have subscribed to the murder of their own cognitive matrix ([Paraskeva, 2016](#)). The fact that Chinese policy makers and academics are still feverishly borrowing Western curriculum policies and practices re-affirms the long-time effect of modernity-coloniality on the colonized ([Maldonado-Torres, 2007](#)).

Nevertheless, I have also argued that, with its rising nationalism and fast economic development in the past few decades, China is striving to recover its cultural soft power to maintain its Chinese characteristics on the global platform (see, [Zhao, in press](#)). Toward that end, more and more traditional-cultural discourses are being re-invoked and re-generated to counter the Western power and foreground its Chinese features. Within such a context, it is opportune to say China currently speaks a language of heteroglossia as old Chinese monographs and terms are continuously re-invoked, re-combined, and re-interpellated as glosses or counter-glosses of Western discourses. Such a mixture of discourses makes the expression of epistemicide more entangled and the unpacking of epistemicide more complicated. Epistemicide expresses itself less in unpacking what forms of discourses are circulating, than in how the varied forms of discourses are ordered, juxtaposed, interpreted, and manipulated by the Chinese academicians and policy makers. In other words, it is through unpacking the academicians’ and policy makers’ way of understanding and reasoning the varied discourses in assemblage that we can glimpse into the operativity and expression of epistemicide. Epistemicide links itself not only to the circulating discourses, but how the modern Chinese language and schooling discourses, whether Western or traditional Chinese, are *interpreted* semantically, culturally, and cross-culturally, and more importantly, in the *English* language to the international audience (see, [Zhao, in press](#)).

For example, I have examined language and discourse as both a colonial and de-colonial gesture, a very site of epistemological dilemma ([Zhao, 2020a, 2021, in press](#)) that confronts China’s ongoing competency-based curriculum reform. China released its *Core Suyang Definitions for Chinese Student Development* in 2016, invoking the traditional-cultural notion of *suyang* as both a gloss and counter-gloss of the English terms of competency, skills, and literacies. Claiming to be more than a replica of the OECD’s and USA’s frameworks, China’s *suyang* definitions also foregrounds the Confucian tradition of *learning, body-cultivation (xiushen), and governing* in nurturing holistic student development. However, I have argued that Chinese policy makers’ and academics’ efforts of making a Chinese characteristic competency-based curriculum are thwarted by their unconscious subjection to the modernity-coloniality, and the reinvocation of cultural *suyang* discourse is nothing but a linguistic trope ([Zhao, 2020a](#)).

There, I examined how the *suyang* curriculum discourses are *interpreted* semantically, culturally, and cross-culturally in relation to the Western discourses of competency-skill-literacy and found Chinese intellectuals, still largely subjugated to the modernity-coloniality, have subscribed to the murder of their own cognitive matrix ([Paraskeva, 2018](#)) in two expressions. First, Chinese scholars commonly presume a *suyang* = competency ordering and interpret *suyang* merely as a semantic equivalent of competency. The *suyang* = competency ordering well betrays scholars’ subscription to the modernity-coloniality episteme of conceptual thinking, or what [Foucault \(1973\)](#) puts as a representational language and a signifier-signified mode of signification, reducing language to a trap of philology which assumes the a priori existence of grammatical arrangements in a language in which meaning is deduced from the grammatical structure. Second, even though *suyang* foregrounds cultural elements of “desirable character-traits” and “emotions-attitudes-values” (on top of the Western/modern “key competencies-skills-literacies”), they are largely treated as psychological traits, ordered in no way different from competencies-skills-literacies and failing to explicate the cultural-traditional episteme of “body-thinking” ([Wu K. 1997](#)) that goes with a Confucian tradition of *learning, body-cultivation (xiushen), and governing* in nurturing holistic student development.

Inspired by Foucault’s and Heidegger’s thinking on language/discourse and representation, I have bracketed *suyang* as a modern concept and rewritten it into a grammatical form of “su + yang”, probed into the etymological sayings of *su* and *yang*, and explicated

a Chinese (w)holistic body-thinking (Wu, K. 1997) episteme that could be nurtured within the cultural notion of *suyang* (see, Zhao, 2020a, 2021, in press). The Chinese notion of “body” registers not the physical or biological body of the modernity episteme but a “psychosomatic self” (Ames, 1993, p. 165), a (w)holistic mind-body-heart ensemble. Thus, rather than “bodily thinking” or “thinking has a bodily dimension”, the (w)holistic “body-thinking” enacts thinking ontologically such that the body is thinking and thinking embodies itself in bodily engagements. This (w)holistic body-thinking epistemically responds to the Confucian “body-cultivation” (*xiushen*) in that it is by playing/living varied contextualized roles that a Confucian person learns to make his/her personhood in relation to others, not as a foundational and autonomous individual like “the learner”. This (w)holistic body-thinking episteme opportunely re-treats the Confucian virtues or character traits such as “human compassion, righteousness, ritual propriety, wisdom and trustworthiness” no longer as being reducible to a modern conceptualization of ideas. Cultivating such virtues becomes a mode of being to be lived and practiced, say, through parents’ bringing up the children and children’ repaying their parents by showing filial piety and reverence when their parents get old (Zhang X., 2015). In other words, I turned language into a de-colonial tool, rendering visible a silenced and different genealogy of thought (Paraskeva, 2018), which provides an alternative paradigm and direction for reconfiguring China’s competency-based curriculum beyond the grip of Western/modern discourses/languages and frameworks.

Re-turning to the cultural-historical-philosophical foundations of China’s curriculum knowledge

As shown above, examining language as epistemic traces and unpacking translingual practices of translation help to draw our attention to what is otherwise marginalized or suppressed Other cultural-historical forms of knowledge. Yet, as I have elsewhere argued (see, Zhao, 2019b), explicating such Other cultural-historical epistemes as they are and not in the representation of the modern present is hardly possible without a historical mode of inquiry, because, as Heidegger (1966/1996) rightly argues, “thinking itself can be transformed only by a thinking which has the same origin and calling”. To Heidegger, a historical inquiry is distinct from the usual history of ideas mode of inquiry, namely, historical reporting of the various opinions, viewpoints, and propositions, about something through the centuries. The history-of-ideas mode of inquiry already presupposes the static existence of something and only asks about the formula and the definitions of the essence of something, whereas a historical mode of inquiry asks about the happening and the movements that something has taken historically, of which the formula and the definition are only the residuum and sediment. Furthermore, Heidegger (1967) argues that the historical happenings and movements of something are not necessarily the already established and past actual movements, but could also be in a form of *acquiescence* (my italics) no longer going on in the present yet still constituting as a basic form of the presence of the history. This is because what is merely actually past does not exhaust what has been. The purpose of this historical mode of inquiry, Heidegger further argues, is not to merely acknowledge how something was before, but to pose for decision how essentially it still is today. Put differently, the detour into the past is aimed to access the present.

To Foucault, such historical mode of inquiry is archeological or History of the Present which he grants a privilege over all the other disciplines in his discussion about today’s human sciences. He clarifies that discourses are linked in a historical fashion such that the present is an effect of conditions of historical possibilities. Henceforth, in studying an ensemble of theoretical discourses concerning language, economy and living beings in *The Order of Things* (1973), Foucault didn’t try to establish the a priori possibilities or impossibilities of such knowledge but do a historian’s work by showing the simultaneous functioning of these discourses and the transformations that accounted for their visible changes. In other words, archaeology concerns knowledge constitutive in its condition of possibility rather than a history of ideas or sciences. It is an inquiry that, by going back upstream in the history of discursive formations, knowledge, and practices, seeks to discover on what basis knowledge and theory became possible (Agamben, 2009). This archaeological-historical mode of inquiry thus involves an epistemological shift from viewing time, history, and tradition as being some static, irreversible and irreducible essences (data) to re-configuring them as happening, events, movement, and moments of arising possibly external to any timeline. The aim of disrupting the fixed and canonized tradition and history is to set back into motion the original inner happenings of something by tracing its way back to its self-laid grounds to found itself anew out of them. This new founding and finding are expected to shed new light on and render accessible the otherwise enclosed present educational reforms and discourses (see, Zhao, 2019b).

The field of curriculum studies lacks a historical perspective in general (Phillips, 2014) even though it is highly needed to reclaim some “historical-philosophical-cultural motifs” (Kazamias, 2001, p. 37) as the very root of education to re-humanize the currently predominant neoliberal order (Baker, 2009; Popkewitz, 2008, 2013). Since Herbert Kliebard’s classical historicization of the American curriculum from 1893 to 1958, historical unpacking of educational thinking and practices in the Foucauldian sense of the history of present has emerged, if not flourished, as a new field. For example, Bernadette Baker’s (2009) edited book, entitled *New Curriculum History*, indexes the challenges in locating the irreducible “heritage” of transnational curriculum studies which meanwhile does not centralize curriculum, education, knowledge, and power as boundary fields or reproduce the second-order normativity embedded in the a priori definitions of these terms. Thomas Popkewitz et al.’s edited book (2017) problematizes the “reason” of schooling by historicizing the conditions of possibilities of curriculum, pedagogy, teacher education, and the sociology of knowledge in varied cultural (con)texts. Zazanian and Nordgren (2019) edited a special issue of the Journal of Curriculum Studies that revisits historical consciousness as a theoretical construct and explores its broad understanding for contemporary education and educational research.

I did my doctoral studies with Thomas Popkewitz and Bernadette Baker at University of Wisconsin-Madison. Inspired by their historical unpacking of transnational curriculum knowledge, my doctoral research was to discover on what basis knowledge and styles of reasoning about China's education and curriculum become possible, and within what space of order they are constructed. It explicates the historical-cultural a priori which makes it possible for teaching, learning, and the teacher-student difference in past and present China to be said and enacted as they were and are. In other words, my doctoral research didn't track the historical vicissitudes of China's education and curriculum reform; rather, it got deeper into the epistemological field, examining the positivity of knowledge as well as the historical-cultural principles as conditions of possibility for today's educational thinking and practice in China on a cross-cultural landscape (see, Zhao, 2019b).

For my doctoral research, the turning-point signpost is my serendipitous discerning of the prevalent yet silent "wind-education" discourses, literally put, "school/teaching/learning wind" in contemporary China's schooling. The Heideggerian-Foucauldian historical-archaeological mode of inquiry enabled me to ask not what "school wind" means but how it is historically possible for wind and education to intersect in Chinese culture. Such a discerning set me on to a journey of dancing with the "wind", or rather, following the dancing "wind" to be open to the (con)textures and (over)tones of the Chinese language itself and ancient texts. For example, rather than "air in movement" as defined by the Oxford dictionary, the Chinese character of "wind" etymologically says "wind blows, and insects get germinated and transformed within 8 days" (Shuowenjianzi), disrupting the modern-western conceptual style of reasoning and signifier-signified mode of signification. In other words, the Chinese "wind" has an inherent sense of "transforming" or as Kuriyama rightly puts it, "the fascination of the Chinese winds lay in their power to *transform*" (my italics) (1994, p. 23). It is this inherent "transforming" sense that links Chinese "wind" back to Confucian teaching and learning narratives, say, "wind (is) teaching, wind moves and teaching transforms" (Han Preface to *Book of Odes*, around 200AD) and "gentleman's virtue is (like) wind and petty man's virtue is (like) grass; when wind blows across it, the grass must bend" (*Analec*s, around 500BCE). Put succinctly, the imagination of Chinese "wind" instead looms large in and across domains of education, politics, poetry, and Chinese medical body (see, Zhao, 2019b).

Following further the dancing "wind" finally exposed me to Confucius' own envisioning of teaching and learning as expressed in his commentary on one Yijing hexagram called *guan* (observation) with a hexagram-image of wind blowing over the earth (see, Zhao, 2019a, 2019b, 2019c). This hexagram, itself having nothing to do with teaching and learning, zooms on one ritual scenario where the Son of Heaven washed his hands but not yet offered the sacrifice, with a pious outlook and in front of his subjects. Confucius added a couple of comments, leveraged upon the "transforming" sense of Chinese "wind", and envisioned it into an ideal, exemplary and contingent, teaching-learning movement that happens like wind blowing over the earth. Indeed, I was accidentally exposed to the Yijing *guan*-observation hexagram, which I argued as an originary, not original, re-source of the entire Confucian teaching and learning, and the notion "wind" can be re-viewed as the signature language of Chinese education (Zhao, 2019a, 2019b). Neither point has so far been discerned, let alone scrutinized in scholarship on Confucius and Confucian educational culture in China and beyond. Here, "originary" needs to be understood in the sense that there is always something unsaid that could be further tapped, that what was said within the Chinese notion "wind" is always in being in advance of it, and yet is never expressly thought in its own right and as the Originary.

In other words, Heideggerian and Foucauldian historical-archaeological mode of inquiry enabled me to disrupt and suspend the modern Westernized representational thinking, setting back into the motion the original inner happenings of the presently silenced "wind-education" rationale by tracing its way back to its historical-cultural-philosophical self-laid grounds to found itself anew out of them. The historical-cultural-philosophical returning is not for a nostalgia purpose, but to better cut into the present, exposing deeper the coloniality of knowledge, being, and power of modernity on current Chinese people, say, my examination into China's competency-based *suyang* curriculum reform as detailed above. Such historical-cultural-philosophical returning provides not merely an alternative thinking of China's curriculum, but rather, an alternative thinking of alternatives. My "wind" research along a detour-and-access (detouring into the Western scholarship to access the Chinese self, and detouring into the Chinese past to better access its present) cartography of knowledge, language, and education blurs the geographical and epistemic boundaries of East, West, past, present, human subjects, and the researched objects. Instead, I am thrust into a new pluri-verse where to engage in varied forms of knowledge. Within such pluri-verse, language is no longer assumed to exist as a legitimized and enclosed system; meaning is no longer decided by the grammatical arrangements of statements; education is no longer about a neoliberal seeking of outcome and profit; and doing research is no longer merely to apply a pre-given framework to certain contexts. My dancing with the "wind" is more of an itinerant encountering, a de-centering and re-centering of various signposts, a processing, something that can only be recounted backward rather than anticipated ahead of time (see, Zhao, in press).

Re-turning to the cultural-historical-philosophical foundations of international curriculum: some on-going efforts

Currently, I am pushing further the cultural-historical-philosophical foundations of China's curriculum studies in deeper connectivity with the Western scholarship, as well as editing books on furthering transnational dialogues on the cultural-historical-philosophical foundations of international curriculum studies.

For the former, I am writing my second monograph, *Edusemiotics, (New) Materialism, and (Body) Governance: Flashpoints in 21st Century Education in China and Beyond* for the book series, *Flashpoints: Education in the Age of Interconnection*, edited by Baker, Saari, and Prasad for Routledge. This project is to revision the current rhizomatic "ideal" and de-historical linking of culturally distinct

onto-epistemologies, worldviews, languages, spatiotemporalities, and styles of reasoning in social science and educational research. Such rootless “ideal” connectivity has engendered trans-philosophical flashpoints and ethical difficulties for researchers, practitioners, and policymakers in education and beyond. With China as its locus of analysis, my ongoing book project unpacks the technologies of interconnection, broadly conceived, in (re)producing onto-epistemic contestations and clashes on the issues of meaning, being, reality, language, knowledge, body, and governance, and in educational settings. Using edusemiotics, new materialism, and Foucault’s governance theory as three expressions of the latest cultural-philosophical flashpoints, it hopes to provide a healthier intellectual interconnection, historicizing the dynamic collisions, confrontations, and merging of trans-philosophical flashpoints as events, illustrating the distinct worldviews, cosmologies, languages, spatiotemporalities, and rituals not as essentialized “ideas”, but in their fluidities (see, [Zhao, forthcoming](#)).

I have also expanded such transnational “epistemic” connectivity issue in two other projects – one book project for Routledge (see, [Zhao et al., 2022](#)) and one journal special issue for *Discourse* (see, [Zhao and Popkewitz, 2022](#)). Both projects bring into international curriculum and educational studies a relational “epistemic” network to re-examine knowledge translation within and among nation-states on a global landscape both historically and at the present. It explores the trans-national and trans-cultural negotiation, translation, and confrontation of varied historical-cultural-philosophical *epistemes* in their material implications within the (curriculum) modernization and globalization movement. Specifically, it explicates the epistemological groundings of varying forms of knowledge in crisscrossing as well as the historically specific conditions for the happening of “epistemological colonialism”, i.e., the hidden or explicit marginalization, eclipse, or overriding of one cultural form of knowledge by another on a global landscape, whether within or cross nation-states, and in connection with economic development and power struggle.

Other than that, I recently finished a book project with Daniel Trohler on *Euro-Asian Encounters on 21st-Century Competency-Based Curriculum Reforms: Cultural Views on Globalization and Localization* (see, [Zhao and Trohler, 2021](#)). Provoked by the on-going competency-based curriculum reforms on a global scale, this edited book examines where such global framework as OECD’s core competency definitions is rooted in and how they are borrowed, resisted, and/or recontextualized in some European nation-states with a Protestant educational-cultural heritage and some Asian nation-states with a Confucian educational-cultural heritage. Put differently, this book foregrounds the roles that varied mechanisms, say, history, culture, religious attitudes, ideology, and state governance, play in nation-states’ recontextualization of global curriculum policies and practices beyond a simplistic and dualistic globalism/power and nationalism/resistance dynamic. In so doing, it provides a global context to better understand individual nation-state’s on-going curriculum reforms and school practices. The selection of the two educational-cultural systems and wisdom of thought, the Protestant and the Confucian, also provides a unique springboard for conducting international curriculum studies beyond the usual confinement of geopolitical nation-state construct.

“Returning to the historical-cultural-philosophical foundations” to better cut into the present schooling practices in China and beyond

In the 50th anniversary issue of *Journal of Curriculum Studies*, [Deng \(2018\)](#) critiques that the curriculum field has somewhat been transformed into a kind of “postmodern cultural studies” that encompass an array of topics but neglects its core subject – practice and the inner work of schooling as a complex institution as its basic concern. While it is an opportune critique, I have been trying to translate my historical-historical-philosophical unpacking of curriculum knowledge into classroom teaching and learning, as an historical inquiry is to better cut into the present. Specifically, I explore the possible challenges, new openings, as well as intervention strategies, of embodying and translating the historical-cultural-philosophical thinking into classroom practices to enhance teaching and learning efficacy at the nexus, and as the (dis)assemblage, of tradition and modernity, East and West.

For example, China’s Ministry of Education launched a “classroom revolution” in 2017 that intends to transform current teacher-centered pedagogies and rationales with brand-new philosophies and technologies and hopes to cultivate students’ higher-order thinking skills. However, my observations of China’s frontline teaching and learning over the years pinpointed an epistemological flashpoint that enthralls teachers in their pedagogical reform. Namely, teachers commonly believe that their commonly adopted teacher-centered didactic (old Confucian) pedagogies are not conducive to students’ thinking cultivation and yet they have no other choice but to continue such practice due to testing pressure and institutional constraints. Nevertheless, my cultural-historical-philosophical unpacking of China’s (Confucian) curriculum knowledge helps disrupt such naturalized (mis)belief and some stereotypical (mis)understandings of Confucian teaching and learning, demonstrating instead an epistemological compatibility between Confucian didactic (which I term “do-after-me”) pedagogy and students’ thinking cultivation.

Using this epistemological re-understanding as a new entry point for classroom research, I did a case study with two math classrooms through an ethnomethodology approach and as a teaching intervention project on two layers (see, [Zhao, 2020b](#)). First, I explicate the presumed epistemological clash that the teachers have between the claimed Confucian pedagogies and critical thinking. Second, I mobilize an unrecognized yet educative ‘repair moment’ in a Chinese math classroom, generating a possible re-conjoining between teachers’ self-despized yet habitually implemented ‘Confucian do-after-me pedagogy’ and critical mathematical reasoning. Through observations and interviews, I illustrate how this ‘repair moment’ can become pedagogically significant, overturning teachers’ naturalized (mis)belief, redeeming them from the moral-practical dilemma, and cultivating their critical pedagogical consciousness. In so doing, I showcase how to employ a philosophical-plus-empirical paradigm to do classroom research in China and beyond.

Epilogue

The field of (international) curriculum studies, as Pinar (2008) and Deng (2018) review, has indeed grown into a rhizomatic landscape. While practice and the inner work of schooling as a complex institution are still one of the basic concerns of curriculum research, there are many ways to approach them and often times roundabouts and new starting points are needed to try to get out of the grip of the modernity-coloniality trap. As Paraskeva (2016) and others rightly aver, curriculum epistemicide has reached a “quasi-irretrievable point” (p. 3) and continued to intersect with the daily praxis of schools in and beyond the West. The happening of epistemicide, however, is not only an effect of Western power hegemony, but also anchored in a fabricated eugenic claim that Western epistemological perspective is “unique and the only cognitive possible” (p. 3). For example, OCED’s and USA’s core competencies-skills discourses have become dominant ones global wise, suppressing and overwriting alternative local discourses and forms of knowledge in developing countries. The fact that many countries in the world are still jumping on the competency-based curriculum reform wagon, hoping to go global with the more advanced West, shows that non-Western countries are still naturally taking the Western super-discourses of “competencies” and “skills” as epistemologically better, reproducing Western hegemonic curriculum knowledge (above local knowledge forms) in non-Western countries before they know it.

To suspend the “darker side” of the Western modernity-coloniality of knowledge, power, and being, we need to work toward a global “cognitive justice”, that is “sentient of the wor(l)ds behind and beyond the Western epistemological platform, wor(l)ds that are non-monolithic” (Paraskeva, 2016, p. 86). Anticipating a cognitive justice worldwide calls for a new pluri-verse of varied epistemes and cultural forms of knowledge. It pushes the theorists into a pluri-directional path, allowing us not only to start anew from the beginning of the West, but also from a new beginning point, i.e., the non-West, hoping to render visible “a silenced and different genealogy of thought” (p. 80). My research trajectory of re-turning to the cultural-historical-philosophical foundations of China’s curriculum knowledge with new implications for international curriculum research, as explicated above, is one such decolonial effort. Just as Friedrich Hölderlin says: For as you began, so you will remain.

The term “curriculum” has multiple definitions. It is a contested term that reflects the historical, cultural, and epistemological characteristics of curricula, as well as institutional and political conditions. The most basic curriculum question is often formulated in terms of “what should count as knowledge” (Deng and Luke, 2008). Thus, the curriculum research area comprises substantial aspects, such as the purpose of education, the teaching content, and the knowledge expectations of the learners, as well as different approaches to address the relationships between society, knowledge, pedagogy, learning, and assessment. Researchers of curriculum theory tend to be interested in two or more of the three arenas—the societal arena, the programmatic arena, and the classroom arena—as well as the relationships between these different arenas. Thus, curriculum research includes processes of decision-making on different levels of the school system by different actors in accordance with different national traditions and regulations. During the 2000s, educational policies at both the international and national policy levels captured the interest of curriculum researchers. The curriculum research literature reminds us that there are different ways to understand and approach the relationship between the learner, the school, the school district/municipality, the state, and society. Curriculum researchers are also interested in how curriculum texts explicitly or implicitly influence power relations between teachers and students, teachers and the school as an institution, and the school and external stakeholders, such as the government, professional associations, and employee organizations.

The seminal book *Understanding Curriculum* (1995) by William Pinar and associates represents an important contribution to the contemporary history of research and theorizing in the American curriculum field. In particular, the book addresses the reconceptualization of the curriculum field to capture the curriculum as different texts representing various discourses. The book is still highly relevant almost 30 years after it was published. Curriculum can be approached in different ways: as a political, racial, and gendered text, as well as phenomenological text emphasizing the lived curriculum.

In this chapter, we explore the field of research through the lens of two curriculum theory questions: *How can we understand the organization of the school as a societal institution?* And *How can we understand the organization of knowledge in school?* These focus areas have been debated and have changed over the past two decades in Europe and other parts of the world. The first part of the chapter highlights the increasing interest in educational and curriculum policy at the international level. Even if curriculum policy is basically a national or regional responsibility, there is an interest from intergovernmental organizations (IGOs) to influence policy formation. The second section explores different modes of governing and governing trends for curricula over time. The third part of the chapter highlights the current debate on what sort of knowledge best underpins curricula and the role of realism in different knowledge concepts. The fourth and final sections present the main points in a concluding discussion.

Increasing global interest in the policy of national school systems

During the latter half of the 20th century, the term *globalization* emerged, characterized by fundamental changes in our perceptions of distance in time and space. Globalization concerns the intertwining of social relations and social activities “at a distance” with those in local contexts. In this dialectic between the global and the local, both the individual and society are interrelated to a global milieu (Giddens, 1991). The development of globalization, crossing national borders of economy and communication, has simultaneously led to the internationalization of educational discourse. It has also resulted in a policy-directed international education comparison based on an interest in policy problems and solutions. Thus, international knowledge comparisons, such as the

Program for International Student Assessment (PISA) implemented by the Organization for Economic Co-operation and Development (OECD), are concerned with a policy agenda, which is often presented as “self-evident” and with an aim to inform others engaged in similar policy definitions and policymaking (Alexander, 2001). The global trend has evoked an increasing interest in comparative research in areas such as pedagogy, curricula, and policy transformations at the intersection of the global and the national/local levels.

The phenomenon of globalization, based on an ideology of modernity, can be critically examined from at least three different perspectives (Anderson-Levitt, 2008). First, world-system theory admits the material and economic power in globalization but claims it has been imposed by the most dominant nations on other countries. Consequently, if there are certain international convergences in curricula across regions and nations, this is because it is in the interest of powerful nations and international organizations. Second, world-culture theorists, who base their theories on neo-institutionalism, argue that ideologies and ideas, rather than material causes, attract international collaborations between states, organizations, and individuals. Rather, it is a cultural notion of what is thought of as modern and global competition among states that motivates governments to borrow ideas internationally. Third, a critical perspective on modernity and globalization is represented by postcolonial theory. From a post-colonial perspective, ideas matter, but they matter in relation to power. There is asymmetry in the value of different ideas related to the different origins of ideas. For a policy idea to be perceived as important and influential, it needs to be disseminated through powerful and rich actors, both nations and international organizations. By contrast, those who are assumed to receive the ideas are considered to be subordinated as independent actors rather than active players based on their own knowledge and experiences. As Rizvi and Lingard (2010) noted, the pressures for educational change have emerged not only within national systems but also from IGOs, and this has been the case particularly for nations in the Global South. According to Anderson-Levitt (2008), official curricula are becoming more uniform around the world, especially regarding elementary subjects. However, when it comes to how curricula are structured, locally interpreted, and transformed into actual teaching, there are broad variations.

The process of transnational generalizing of curricula and pedagogy across borders has often proceeded as part of development programs, without much criticism. However, policies do not always travel well. The policy solutions are part of “policy selections,” characterized by the inclusion of some educational research and the exclusion of others. As a result, many education systems now encounter policies of standardization of knowledge achievements in curricula where equity is rationalized to mean sameness. According to Luke (2013), this policy movement represents an ideology of marketization and standardization supported by multinational educational enterprises and other international actors. Instead, Luke (2013) argued that policy borrowing needs to be considered from an understanding that effective education policy is often highly context-dependent and therefore cannot move freely across cultural, social, and historical traditions. In addition, the trends toward a global curriculum solution focus mainly on measurable goals, while leaving other goals, such as the democratic goals of civics, civility, language, and culture, outside the curriculum. However, these global processes do not affect all educational systems in the same way.

Rizvi and Lingard (2010) noted that policy studies and curriculum studies are usually considered separate arenas without any direct connection to each other, either theoretically or practically. However, through globalization, the gap between policy and curriculum research has been narrowed, and schooling, curriculum, pedagogy, and evaluation are currently presented in terms of solutions in a discourse of global challenges. Thus, education policy reform is now intimately linked to the international reframing of how to understand curriculum, pedagogy, and evaluation. An important feature of a globalized education policy is the notion of accountability and a major concern for testing. Increasingly, national governments and national educational actors have begun to govern the school system by using standardized tests, both nationally and internationally. Thus, it can be argued that testing has become a central element in policy regimes and that policymakers are trying to influence local school practices through various tests with implications for both curriculum and pedagogy (Rizvi and Lingard, 2010).

Modes of curriculum governance

In the modern history of curriculum development as a governing tool, countries have followed different patterns and routes. European countries such as Germany, France, and the Scandinavian countries have a tradition of state-based curriculum making (Westbury et al., 2016). In countries like the United States, Australia, and the United Kingdom, curriculum development was traditionally in the hands of local authorities and schools, and the idea of a curriculum controlled by the state was highly contested. In the last 30 years, developments have indicated that curriculum has become a national concern and a part of the jurisdiction of state governments in most of these countries (Biesta and Priestly, 2013, pp. 230–231).

Despite the convergence toward recognizing the national level in curriculum making, historical trajectories and institutional settings show that the emergence of a national curriculum has been legitimated in different ways. As shown by Hopmann (2003), two different approaches to curriculum control and evaluation were observed by the end of the 20th century. Continental European and Nordic countries followed a process-centered approach characterized by the enhancement of the independence of the teaching profession and where *Didaktik* represents the common core of professionalism. The Anglo-Saxon tradition followed a product-centered approach where efficiency becomes the core of the profession and “the best teacher is the one who gets his students to ‘stand up and deliver’ at the right time—whatever the cause for their ability to do just that might be” (p. 472). While the curriculum control within a process-centered approach is input-based with plans and frameworks as the main instruments, the product-centered approach is output-based with learning outcomes and standards as the main instruments.

These differences reflect how countries have dealt with processes of centralization and decentralization in the policy of curriculum making. This issue has been a concern throughout modern schooling. The concept of governance, although slippery, is relevant for understanding the policy and politics of curriculum making. Governance is “the interactive processes through which society and the economy are steered toward collectively negotiated objectives” (Ansell and Torfing, 2016, p. 4). This definition underlines the importance of interaction with regard to the exchange of ideas, resources, and competences that are required.

Centralization, decentralization, and recentralization

Contemporary research on curriculum governance has paid great attention to the processes of centralization and decentralization. In the 1970s and 1980s, many Western countries promoted decentralized modes of governance. One line of argument called for replacing a more central administrative model of governance with a model that gave the profession and the school a more influential role (Beare and Sturmann, 1991). Another approach to decentralization called for a participatory model that involved the profession and the educational administration while inviting a wider range of participants, such as parents, local communities, and social movements, to play roles in the decision-making.

Curriculum reform initiatives in the 1980s and 1990s in the Nordic countries followed trajectories of decentralization that moved some of the power over the decision-making processes to the local level and the schools (Lavonen, 2017; Lundgren, 1990; Mølstad, 2015; Alvunger and Wahlström, 2021; Wermke and Prøitz, 2021). However, the story also shows differences in the trajectories of Nordic countries. The curriculum reform in Norway in the 1990s represented a recentralization in which the regulation of the content of the curriculum became more detailed than in the former curriculum. This change reflected the idea of a strong state combining central management with social democratic confidence in the state as a guarantor for the fair distribution of welfare services (Telhaug et al., 2006). In Sweden, the strategies chosen in the 1990s included the marketization of the school system with the introduction of school vouchers (Wahlström, 2014; Wermke and Prøitz, 2021). According to Wahlström (2014), the 1991 school reform of decentralization in Sweden led to a denationalized conception of education characterized by the state’s withdrawal from the national policy arena in favor of transnational policymaking and a displacement from a more corporative to a more state-centered approach. The state’s presence was strengthened in terms of governing through accountability and results.

Weiler (1990) described three commonly advocated rationales for greater decentralization:

1. Decentralization as the redistribution of power.
2. Decentralization as a means of enhancing the efficiency of educational governance.
3. Decentralization as a means of enhancing a culture of learning.

Weiler (1990) argued that these rationales encounter substantial difficulties despite their claims. The notion of decentralization as a redistribution of power may be counterproductive to effective governing of education and attempts to secure equality and a unified educational system for all. The second notion of decentralization as a means of enhancing the efficiency of educational governance, represents a critique of public administration and follows ideas from new public management (NPM) such as a belief that decentralized system can utilize available resources more efficiently. Weiler (1990) also questioned this rationale, as it appears to depend on certain premises such as possibilities for different local stakeholders to have an influence on the educational system. The third notion of decentralization as a means of enhancing a culture of learning means that the local context and cultural arrangements are considered when determining how to regulate education. However, Weiler (1990) argued that the claim for learning may be less oriented to the particularities of the local culture; rather, global terms that include more universalities and traveling ideas characterize the discourses of learning.

Despite these criticisms of the three rationales, an overt commitment to decentralization in educational governance has important political utility. Weiler (1990) noted that “it becomes an important vehicle for both the management of social conflict and for what I have called ‘compensatory legitimization’” (p. 51). Weiler (1990) continued as follows:

The frequent wavering between centralized and decentralized modes of policy behavior – or, to be more exact, between decentralization rhetoric and centralization behavior – may very well have its cause in this difficult task of walking the fine line between the conflicting imperatives of control and legitimacy (p. 55).

Weiler’s (1990) contribution seems relevant to the ongoing debate on decentralization. Walking the fine line means balancing political and professional power as well as central and local power. Furthermore, the distinction between rhetoric and behavior is important when studying modes of governance.

Based on data across 33 countries (mostly OECD members and European countries) from the PISA surveys in 2000 and 2015, Jeong and Luschei (2018) concluded that, despite the narrative about decentralization, school governance appears to be moving toward centralization, most dramatically in the area of curriculum and instruction. Although the authors pointed to some important limitations, such as the fact that the measure of teacher responsibility was based on questionnaires administered to school principals and that perceptions of autonomy may not be a perfect proxy for actual autonomy, they asserted that centralized governance has resulted in teachers losing their power and responsibility in educational classroom decisions. Conversely, principals are

maintaining or increasing their responsibilities (p. 299). This point is interesting because it calls for more power-sharing arrangements between governments and principals. Jeong and Luschei (2018) asked whether this trend is a type of “neo-centralization.”

In Nordic research and elsewhere, scholars have highlighted municipalization as a central government strategy (Verger et al., 2016; Wahlström, 2020). While this approach can be viewed as a strategy of decentralization at the local level, it may also mean less power for teachers and a restriction of professional autonomy.

The arguments above, which have been used to advocate for greater decentralization, can, as previously mentioned, be recognized in the arguments put forward within the discourse of NPM.

From NPM to network governance

The NPM policy approach that came onto the scene in the 1980s altered the governance of educational institutions by downsizing government regulations, decentralizing the governing of schools to local levels, introducing results-based performance indicators, initiating a process of commodification of the public sector, and implementing privatization and consumer choice (Theisens et al., 2016; Verger and Curran, 2014). Following NPM policies, the state strengthens its role as a regulator, evaluator, and distributor of incentives to providers (Verger and Curran, 2014). While some of the policy measures connote neoliberal ideas, others, such as curriculum content and school-based curriculum development, do not.

Several researchers have pinpointed the recent transformation of network governance that extends NPM policies. They described these changes as a re-regulation of society through the ways in which these networks of actors make use of new governance tools (Helgøy et al., 2007). Theisens et al. (2016) emphasized that the state is still central in the political context, with public sector organizations operating as knowledge providers. Reform policy today emphasizes state-centered solutions, while acknowledging the mix of governance mechanisms and institutional complexity that characterizes the public sector and has generated renewed interest in collaborative governance (Karseth and Sivesind, 2022). As a result, policymaking involves multiple actors, including international actors, non-state actors, interest groups, and professional and governmental actors, meaning that governments are under constant pressure to interact and negotiate with and mediate among a plethora of policy actors (Steiner-Khamisi et al., 2022). The arguments put forward in policymaking call for broader involvement and more deliberative processes.

Although the picture of policy governance emphasizes network, assemblages, and temporality, state bureaucracies are still operative institutions that govern reform processes in the Nordic countries, but they are “less driven by politicians, more planned, and less contested by the unions, and there is more public involvement” (Greve et al., 2016, p. 201). This condition is certainly true when it comes to national curriculum making, as evidenced by the recent curriculum renewal in Norway. The incremental reform that came into effect in 2020 continued with components introduced by the fundamental reform in 2006, such as competence aims and basic skills. In addition, the 2020 reform (LK20) introduced descriptions of core elements in different school subjects, three interdisciplinary topics, and formative assessment. The new curriculum framework also entails a new core curriculum (Steiner-Khamisi et al., 2020; Sundby and Karseth, 2021).

The educational agency, the Norwegian Directorate of Education and Training (DET), orchestrated the process, and the concept of co-creation became a signifier and a mobilizer in handling the complexity of curriculum making (Karseth et al., 2020). The work was organized by establishing a partnership group headed by the Minister of Education and consisting of representatives in leader positions from different teacher and school leader associations/unions, the Norwegian Association of Local and Regional Authorities, the School Student Union of Norway, the Sami Parliament, and the Higher Education Council. Representatives from these organizations constituted a “working group” according to the DET. Some groups were appointed to produce drafts of the core elements of the school subject, while others drafted the school subject curricula. The resulting work was sent out for public responses—and several actors were invited to pose their arguments and suggestions at an early stage—in addition to formal public hearings.

We argue that the process follows the idea of collaborative governance. From a critical perspective, we question whether a co-creation process hides how power unfolds. First, the power of the state is made invisible because of an impression of participation, although the premises for the work have already been established. Second, what appears to be a democratic and open process is, in fact, rather closed and opaque with regard to final decision-making. The capacity to join different arenas to give feedback and suggestions is also uneven. The third point is the types of policy instruments offered by the DET (progress plans, lists of approved verbs, templates for completion, requirements for digitization) that define the space for not only how to write and structure the curriculum but also how to interpret it.

These issues indicate that DET acts as a main vehicle for policy implementation but that it also plays a role in setting the policy agenda by being a core actor in the governance network of cooperation. As such, the division of labor between the Ministry of Education and its agency is rather blurred (Szescilo, 2020). Furthermore, DET also plays an important role in connecting national and international policy agendas by participating in networks orchestrated through the OECD. As previously indicated, education policy reform is closely connected to the international reframing of how to understand curriculum, pedagogy, and evaluation. Through the project known as *The Future of Education and Skills 2030: OECD Learning Compass 2030* (OECD, 2018), the OECD has taken a new step in governing education globally, with a call for redesigning curricula to meet the challenges of the 21st century. To design and implement a future-oriented curriculum, the different national agencies are important players to legitimate and act as knowledge brokers.

Ministerial agencies, such as the DET, are defined as organizations that are formally part of public administration while enjoying considerable autonomy. In the field of curriculum, the DET plays a significant role in not only implementing a curriculum reform but also orchestrating the process with regard to collecting evidence, knowledge, and information and acting as a mediator and interpreter between international reform initiatives and the agenda of national curriculum policy. Moreover, in the case of Norway, the DET is also instrumental in producing digital resources and infrastructure that can be used at the school level. These instruments are not part of legal curriculum regulation and can be described as soft governance tools.

Hard and soft governance in an era of new technology

In the educational sector, researchers have identified a line to walk between governing through hard laws and soft laws. They have recognized a shift from “formal legal instruments to more flexible forms of steering and involving decentral organizations and actors in implementation” (Theisens et al., 2016, p. 468). This trend implies the introduction of more subtle “soft” forms of control linked to the increased use of evaluation and quality control (Hudson, 2007, p. 278).

The use of soft governing tools has been central in an attempt to standardize higher education in Europe. Approaches to regulation are through a political convergence that includes implicit discursive mechanisms, such as language used, knowledge making, and meaning making in general (Le Bianic and Svensson, 2008, p. 573). Despite the lack of hard governance in the form of legally binding laws, the European Union (EU) and the Bologna Process represent powerful driving forces for the processes of national decision-making through coordination procedures (e.g., meetings and recommendations), benchmarking, and monitoring activities (e.g., reviews, reports, and scorecards), and guidelines (e.g., procedures, templates, and checklists). These are typical examples of soft laws providing clear advice to national governments and higher education institutions that normally have been left to academics (Karseth and Solbrekke, 2016). Such advice might be impossible to ignore if one wants to operate under the Bologna Process. The EU policy rhetoric opens the door for agents to develop guidelines and best practice examples that are difficult to ignore at national or institutional levels (Veiga and Amaral, 2012).

Likewise, state authorities’ use of soft digital technology is not only to support learning in schools but also to serve governance purposes in terms of what can be called e-governance (Sivesind and Skedsmo, 2020). School leaders and teachers are increasingly expected to use digital software to collect and distribute digital data to confront challenging issues in curriculum, assessment, and school development. In this sense, digital platforms and software have become necessary to comply with governmental expectations of performance measurement. Digital technologies are now providers of evidence and important actors in identifying what best practice is and what it should be (Lunde and Gunnulfsen, 2020, p. 197). Recent research on digital education governance has leaned on actor-network theory, in which digital curriculum instruments are explored as actors (Lunde and Ottesen, 2021).

Multilevel governance and curriculum policy

As previously mentioned, curriculum governance is complex and takes place at different levels and sites. Researchers from different educational fields of study have drawn attention to understanding intergovernmental relations and the interplay of different levels in the context beyond the national or federal state, as well as the changing dynamic of the state–society relationship (Bache et al., 2016).

From a new institutional theory approach, Meyer (2007) argued that curriculum reform worldwide follows common ideas. Based on an analysis of curriculum research in several countries, he stated that modern world society builds on the idea of “an expansive conception of the individual human person, being a member of a human society as a whole rather than principally as the citizen of a nation-state” (p. 264). Although curriculum researchers have identified significant variations in the implementation and management of reforms, these reforms are not legitimated by references to national structures (Meyer, 2007, p. 265). Hence, Meyer (2007) questioned the role of states in creating global heterogeneity through national reforms.

Researchers have criticized the arguments of convergence and have noted that similar education reforms are translated, recontextualized, and modified in national and local contexts as they spread globally. Nation-states understand and handle global reform manuscripts on curriculum policy differently and adjust their policies to meet global requests and demands (Maroy and Pons, 2019a,b; Nordin and Sundberg, 2016; Steiner-Khamisi, 2009; Wahlström, 2016). Therefore, curriculum work is embedded in a context guided by global policy initiatives, as well as national mindsets and institutional procedures and practices.

Maroy and Pons (2019a,b) offered a theoretical framework for analyzing education policy, particularly accountability policy, to capture the dynamic and interaction between a global policy agenda and deeper-rooted national institutional or political processes. According to their framework, the trajectory of education policy is the product of empirically intertwined dynamics of path dependence, bricolage, and interpretation. Furthermore,

The trajectory leading to vernacular forms of globalization (rather than a convergence of policies deriving from irresistible global discourse or forces) is also shaped by the processes of policy implementation at the intermediate level (regulatory authorities falling between the central authorities and local schools) or at the local level (p. 53).

Finally, the orientations and local meaning of the policy processes depend upon the instrumentation of this policy and how local actors use or do not use different devices and tools.

The empirical findings from Maroy and Pons' (2019b) study support another variant of NPM than the neoliberal one, and the authors argue that the two cases they analyzed (France and Quebec) follow a "neo-statist" trajectory that implies strengthened state power and administrative regulation.

Maroy and Pons (2019a,b) analyzed accountability policy and not curriculum. However, their framework also offers theoretical and conceptual lenses to capture the multiplicity of curriculum governance. Mathou (2022) analyzed the curriculum in the same two cases and concluded that there is not necessarily a convergent movement between competency-based curriculum reforms, NPM, and neo-liberal policies. She highlighted the ever-changing dynamics and complexity underlying curricular policies. Future research needs to examine the processes of recontextualization between and within transnational and national policies and to address how school subjects are defined and laid out in the formal curriculum as well as in the classroom.

Even if curricula reforms differ between countries and different countries respond differently to international debates and influences, the question of curriculum content and its foundational perspectives can hardly be avoided for those interested in curriculum research. Thus, a topical debate is what kind of knowledge the curriculum should be based on. The OECD project *The Future of Education and Skills: Education 2030* (OECD, 2018, p. 3) claims that the organization is "committed to helping every learner develop as a whole person, fulfill his or her potential and help shape a shared future built on the well-being of individuals, communities, and the planet." The OECD suggests the concept of *competences* as the best way to prepare students for a rapidly changing world. The concept of competence is a broad concept that includes knowing, acting, and valuing. However, the concept of competence is based mainly on policies for contemporary society rather than on a deepened interest in theories of knowledge or knowledge traditions. To bring a well-grounded knowledge debate into the educational sphere, there is now an increasing need to explore different knowledge traditions and their basic assumptions about how individuals can develop knowledge about the world. In the next section, three different traditions of knowledge are discussed, based on their different basic assumptions and their potential implications for school knowledge formulated in the curriculum.

Curriculum, knowledge, and the view of realism

In the second section of the chapter, the central interest is the current discussion on the concept of knowledge and its implications for a knowledge-based curriculum. At the center of the debate is humans' perception of reality; that is, how humans can gain reliable knowledge about the world.

With the publications of *Knowledge and Control* (1971) and *Bringing Knowledge Back In* (2008a), the British sociologist of knowledge, Michael Young, has played a prominent role in debates on knowledge and curriculum. In the former text, Young (1971) noted that the questions of how knowledge is selected, organized, and assessed in educational institutions were largely neglected by sociologists at the time. Young (1971) insisted that education is not a product; it cannot be compared to goods manufactured in a factory. Instead, education is about "selection and organization from the available knowledge at a particular time which involves conscious and unconscious choices" (Young, 1971, p. 24). From such a starting point, studies on methods of assessment, selection, and organization of knowledge, as well as the principles underlying them, become central. Moreover, according to Young (1971), sociologists have overlooked the process of transmission of knowledge. The space where the transmission of knowledge from the social culture of society to the new generation is taking place is the curriculum. Thus, the curriculum became a central interest for studies of stratification of knowledge and social control.

In this "new sociology" in the 1970s, in which Michael Young and Basil Bernstein in England and Pierre Bourdieu in France were significant actors, students' educational failure was less related to genetic theories on intelligence and more to socially controlled cultural transmission. The "new" studies in sociology focused directly on the content of education and on the school's internal organization of the curriculum content to different groups of students. The new "interpretive paradigm" emerged in opposition to an earlier "positivistic" and "functional" paradigm. A main critique was that, until then, curriculum researchers had taken the problems formulated by the educators for given rather than formulating their own problems for research on curriculum and pedagogy. While interpretive sociology dominated educational sociology in Great Britain during the 1970s, conflict theory emerged as the dominating critical research approach in educational sociology in the US (Karabel and Halsey, 1976).

A focus in both approaches was on education and differential power. In its early phase, education was seen simply as reflecting the dominating relations of economic and social forces in society. The critical approach concerned the ways in which national school systems and curricula reproduced prevailing power relations. Over the years, a more complex set of contradictory relationships has been recognized in critical curriculum studies, influenced by other traditions such as cultural studies, and feminist and postcolonial theories (Apple, 2003). Drawing on Max Weber, the starting point in critical studies in education was the insight that dominant groups in society have the capacity to impose their own educational and cultural ideals on schools. These ideals become reflected in both what is taught in school and how it is taught. Thus, what counts as knowledge in school is ultimately a political question, even when there seems to be a social consensus (Karabel and Halsey, 1976).

Against this background, Young's book *Bringing Knowledge Back In* attracted a great deal of attention when it was published in 2008. Young was concerned by what it really means that knowledge is "social." In the book, he takes a critical stance to the post-modern tradition, which "appear to provide powerful support for the cultural demands of subordinate groups" but "by arguing that knowledge is inseparable from how it is constructed, they cannot avoid the conclusion that all knowledge, whether based on

professional expertise, research, or the experience of particular groups, is of equal value" (Young, 2008a, p. 22). About 40 years after the book *Knowledge and Control* was published, with its warnings of overlooking the connections between school knowledge represented in curriculum and the social structure of society by taking the cultural content represented in education for granted, Young (2008) now asked himself what he meant more exactly when claiming that knowledge is social.

Young (2008a) is critical of two dominant currents of thought in education. First, there is the longstanding idea termed neo-conservatism, which emphasizes a certain content in the curriculum representing the respective canons of the subjects. Although neo-conservatists' focus of canonical texts, neo-conservatists are not interested in epistemological issues in the first place but are rather driven by the idea that the traditional discipline required in learning subject knowledge also promotes traditional values in society. Second, neo-conservatism has been challenged by a more recent broad discourse on education that Young (2008a) terms "technical-instrumentalism." This conception of education takes its starting point in the need of the industry for skilled labor and the need of the nation to be economically competitive. Within this view of curriculum, education and knowledge are not an end in themselves but rather a means to achieve other goals. Most critical, however, was Young (2008a) of postmodernism and the "linguistic turn," which he believes has led to relativism between different forms of knowledge.

Social realism as a response to postmodernism

Young (2008a) criticized postmodernists for claiming that academic curriculum essentially relies on arbitrary and general assumptions about knowledge and culture and that the curriculum thereby contributes to the perpetuation of social inequalities. When arguing that "knowledge is inseparable from how it is constructed" postmodernists end up with the conclusion that all knowledge "whether based on professional expertise, research, or the experience of particular groups, is of equal value" (Young, 2008a, p. 22). The problem, Young (2008a) argued, is that since postmodernists lack a theory of knowledge, they cannot do much more than disclose power relations in the policy of curricula without offering any real explanations. He considered postmodernists to have a reductionist way of understanding knowledge by treating knowledge as a standpoint rather than a fact. According to Young (2008a), postmodernists highlighted silenced and excluded voices and equated the experiences of these groups with already-established knowledge. From this relativism among different sources of knowledge, Young (2008a) claimed that several problems related to the sociology of knowledge and knowledge as a base for curriculum occurred. One problem is the upholding of the intrinsic autonomy of knowledge. A second problem is that if knowledge is reduced to being the standpoint of any social group, there is no basis for the selection of knowledge in the curriculum. A third problem is that reducing knowledge to experience means that there is no possibility of generalizing knowledge beyond different social situations. The core of Young's critique was directed at the concept of experience, because if experiences of different social groups should represent actual knowledge, there is no longer any sociology of knowledge but only a sociology of knowers, leaving school curriculum without any logic of what should be included and what for.

To solve the problem of holding onto the social character of knowledge without falling into relativism, Young (2008a) suggested an approach to knowledge, which he termed *social realism*. A main argument in social realism is that a social theory can constitute the basis for claims of truth and objectivity, provided that the processes and codes through which knowledge is produced are strictly defined. A second main argument is that some knowledge is objective because it transcends the social and historical conditions of its production. A third basic argument is that social realism acknowledges the precedence of internal cognitive conditions for the production and acquisition of knowledge over external social processes in society. The social realist approach to knowledge and curriculum is social in that it recognizes the role of human agency in the production of knowledge. It is called "realism" because social realists claim that due to the specific processes that are valid for the production of knowledge, knowledge is independent of context. This context independence is what characterizes the difference between knowledge and common sense. Since knowledge is socially and historically constructed, it is always temporary and fallible.

These basic assumptions forming the concept of social realism as an approach to knowledge and curriculum have subsequently been followed up in a series of articles and books (e.g., Young, 2008b, 2010, 2013; Young and Lambert, 2014; Young and Muller, 2010). It has also led to a broad debate within curriculum theory on the concept of knowledge and its relationship to curriculum and school subjects. Some of the more prominent conceptions of knowledge that have become salient in this debate are the concept of transactional realism developed by John Dewey within the American philosophy of pragmatism, and the concept of *Bildung* based on a German historical and philosophical tradition from the beginning of the 19th century.

Experience as a concept of knowledge: transactional realism

Instead of considering the concept of "experience" as something strictly subjective and distinguished from the domain of knowledge, as Young (2008a) does in social realism, Dewey puts experience at the center of his intersubjective and transactional understanding of knowledge. Dewey's conception of philosophy is often thought of as instrumental, where knowledge is sought for, not for its own sake, but for the sake of action. Sleeper (2001) pointed out that this instrumentalism leads to an understanding of action itself as instrumental. Action becomes a means of social change. Sleeper (2001) denotes Dewey's pragmatism "to be a radical form of realism—a transactional realism" (p. 3). Both knowing and thinking represent actions that involve independent reality. "Even reflection is a means of changing, or reconstructing, the world" (Sleeper, 2001, p. 3). Central to this transactional conceptualization of human action and knowledge is the idea that thinking as a form of action is an important force in social change.

Dewey (1916/2008) took his starting point in the individual's interactions with the environment. The environment is the specific part of the physical and social surroundings with which humans actively interact; thus, the environment includes selectivity. This transactional approach between humans and their environment, based on human experiences in terms of knowledge about the environment, transcends the dualism between subject and object. The individual (the subject) is always already from the beginning part of a world full of objects, which means that he/she is always already in contact with reality. The question of attaining knowledge is thus not about bridging a knowledge gap that separates humans from objects but about distinguishing and examining the various objects and phenomena with which humans interact in their environment. Thus, a main concept in Dewey's theory of knowledge is the concept of experience. Experience is, in Dewey's meaning of the term, "the way in which living organisms are connected with reality" (Biesta and Burbules, 2003, p. 28). Experience is not a process going on inside the subject; instead, it is an interactive process which "changes in some degree the objective conditions under which experiences are had" (Dewey, 1938/1991, p. 22). Thus, an experience is both internal and objective. Experience is transactional because of its interactive character and reciprocal impact. Through the reciprocal impact between humans and their surroundings, experience is transactional; experience incorporates the world in human knowledge (Levine, 2019). Getting knowledge comprises the stages of (a) defining the problem, (b) inquiring into relationships of different possible solutions and consequences, and (c) reflecting on what might be the most reasonable conclusion to handle the problem (Dewey, 1916/2008).

As noted above, experience should be understood as a transactional and communicative approach to specific parts of the environment with which individuals interact. Experience is instrumental in developing human knowledge and, thus, being able to handle both social and physical problems in society. However, it is not instrumental in the sense of finding the best practical solution. Instead, both "practical" and "instrumental" are used in a broader meaning than are usually attributed to the terms. Within pragmatism, theories and intellectual knowing are viewed as parts of practical and instrumental processes aimed at gaining new or deeper meaning of an object or a phenomenon. Already achieved knowledge contributes to the quality of successful experiences.

Bildung—an environment of culture

The idea of Bildung has its roots in the neo-humanist tradition flourishing in Germany in the period between 1770 and 1830. In English, Bildung can be understood in terms of "culture" and "cultivation." Wilhelm von Humboldt, a German philosopher and educationist, held a pioneering role in the political and intellectual history of *Bildung*. A fundamental idea of von Humboldt was that humans need to be both contemplative and active. The noun *Bildung* is derived from the verb *bilden*, "to form." For their activities, people need the world to live their lives and gain knowledge, but they also need the world for their inner cultivation and development. While the world is influenced and understood through human thought and action, it is also the source of the formation of the inner moral and intellectual fulfillment of the individual. Embedded in the theory of Bildung is the dialectic between human activities in the external world and inner reflections on these activities within the individual. This dialectic is important to uphold for the individual not to lose oneself in a fragmented world. Thus, in the case of Bildung, subject knowledge in a single subject is insufficient. It is only when the connections between different knowledge fields transform and extend humanity in our individual minds that Bildung occurs. The individual's freedom is a prerequisite for social life and social contacts because it is only in a state of freedom that people can claim their personal autonomy that arises from their formative inner cultivation (Lüth, 2000).

Inherited in the tradition of Bildung is the insight that it is not the academic disciplines, but rather life as a whole, and the individual's part in that whole, that forms the basis of Bildung. The understanding of life in this context is culture, drawing on the philosophy of Wilhelm Dilthey and the foundations of the human sciences. The German concept of (general) Didaktik, built on a tradition of Bildung, represents the task of identifying the content contributing to Bildung through an analysis of the whole culture of life. In classical general Didaktik, academic disciplines are neither the source of content nor the criteria for achievement (Künzli, 2000). With its roots in Bildung, Didaktik is characterized by elements of self-determination, independence, freedom, and responsibility on the one hand, and humaneness, world, objectivity, and the general on the other.

Thus, Didaktik is about the individual in the world, with the intellectual and moral commitments that it entails. The general educational question becomes "What wider or general sense or reality does this content exemplify and open up to the learner?" (Klafki, 1995, p. 22). The content is the mediator of reality, rather than a gap to overcome, since the individual is always from the beginning embedded in a social and historical world of culture. The focus in both Bildung and Didaktik is not on what could be thought of as reality but on what is understood as human culture or human life. A central idea in the German Didaktik is that the presentation of content in itself is insufficient for education to happen. Learning, or Bildung, only takes place in the encounter between specific content that engages a specific individual. "Then, Bildung is what remains beyond this situated engagement" (Hopmann, 2007, p. 115).

The three knowledge concepts and curriculum

Taking Young's (2013) call for knowledge-based curricula seriously, it becomes crucial what concept of knowledge constitutes the foundation for curriculum. Drawing on three historical curriculum orientations (Deng and Luke, 2008), the social realist approach is in line with an orientation of academic rationalism. In this tradition, the importance of the transmission of disciplinary knowledge is emphasized, since academic disciplines are viewed as authoritative sources from which curriculum content is derived. The curriculum orientation of social reconstructionism corresponds with the concept of knowledge as transactional realism. In social

reconstructionism, social contexts, social issues, and futures are central, with the purpose of helping students reconstruct their own analyses and standpoints. This curriculum orientation comprehends school subjects as sources for meaningful knowledge if the knowledge also constitutes the basis for reflective thinking about what this means for individuals and society. *Bildung*, finally, is closer to the curriculum tradition of humanism. Within humanism, the needs and interests of the individual provide the central starting point for selecting the teaching content. The knowledge approach is experiential, aiming at developing the individual's self-realization and understanding of the world through a mutual development of both culture and the individual.

A concluding reflection/discussion

Two questions derived from curriculum theory have structured this chapter: How can we understand the organization of the school as a societal institution, and how can we understand the organization of knowledge in school? A main argument for a globalized impact on educational policy is that the international interest in education policy, even for compulsory schooling, has been growing over the last two decades, with the OECD, the World Bank and the United Nations Educational, Scientific and Cultural Organization (UNESCO) as prominent international actors. The global dimension is reinforced by the fact that different organizations advocate a similar policy message and refer to each other in their argumentation. In this way, international policy has at the same time approached issues that concern the school's governance, the content and construction of the curriculum as well as the view of knowledge underpinning national and regional curricula. The national reforms can be justified with the help of similar vocabulary, but the very design of the reform is determined primarily by the individual country's historical and social traditions regarding education and school system.

In the 1970s and 1980s, several school systems with strong state-centered control over the national school system turned to decentralization as a way to respond to the demands for pluralism in the supply of school, to limit the development of costs, and to increase local influence over the school. This trend of decentralization seems to have succeeded by a movement of recentralization at the beginning of the 2000s as the result of a policy of local accountability and a focus on outcome-based curricula. A major impact on the changing logic of governing the school sector can be attributed to the success of the launch of the NPM. Within this logic, the state governs the school by means of "soft" technologies as evaluations of knowledge results and allocation of economic resources, rather than using "hard" governance technologies in terms of laws and regulations. However, the recontextualization of international policy to national education policy and the recontextualization from national educational policy to curriculum reform are only the first steps toward actual changes in teaching activities. A third step, the process of transformation from curriculum content to actual teaching in classrooms, remains to be explored to a greater extent than has been the case to date.

A more internal debate in the field of curriculum research has emerged in recent years regarding the view on knowledge and the relationships between knowledge and the real world in terms of realism. This new interest in realism linked to the view of knowledge can be viewed as a reaction to recent forms of knowledge that claim that knowledge only represents a linguistic construction of reality without really incorporating the world outside humans in the understanding of knowledge. In this chapter, three concepts of knowledge have been explored in relation to the function of forming the basis for school curriculum: social realism based on the sociology of knowledge, transactional realism developed within the philosophy of American pragmatism, and the German philosophy of *Bildung*, with its roots in the early 19th century. All three concepts relate to the outer world, albeit in different ways. Both *Bildung* and transactional realism understand knowledge as a relation between the human and the world. In transactional realism, society and common affairs are placed at the center, while culture represents the common interest in *Bildung*. Common to both the pragmatist terms of growth and *Bildung* is the human being acting in the world, who learns and develops from their increasingly in-depth experiences. Both concepts emphasize the importance of teaching content that arouses students' interest and commitment. For social realists, the question of "what" to learn is more related to academic disciplines, and in this way, the content is more predictable. Instead, within social realism, the question of "how" becomes central—how should students get access to this content?

Finally, although the two questions addressed in this chapter point to different aspects and theoretical lenses of curriculum research, the questions need to be connected, as they are mutually dependent and deal with the phenomenon called curriculum.

Introduction

Critical realism and social realism have emerged as important approaches within the social sciences and consequently in theorizing the nature of curriculum. Curriculum is inevitably shaped by what we understand the world to be, the way we understand the similarities and differences between the natural and social worlds, how we understand human agency, the nature of knowledge, and how we access knowledge. Critical realism emerged in the 1970s and social realism somewhat later in response to positivism and empiricism on the one hand, and on the other, different relativist approaches now covered under the broad heading of post-modernism (Bhaskar, 2008 [1975]; Bhaskar, 2011a). Critical realism and social realism are often used interchangeably, but it is important to distinguish the different ways in which they are used. Critical realism is a philosophy that has implications for Margaret Archer's social realism (also called the morphogenetic approach) and the social realist school in the sociology of education, but both are elaborated theoretical frameworks that draw on, though are not reducible to, critical realism. Moreover, Archer's social realism has affinities with, but is not the same as, the social realist school within the sociology of education. And, both these approaches differ from transactional realism which is inspired by Dewey's pragmatism. It is important, as Basil Bernstein (1999) explained, to understand the different "languages" within sociology and other social sciences to gain access to the different conceptual systems of meaning within each.

This article first explores the philosophy of critical realism and the ways in which it "under-labors" the social sciences (Bhaskar, 1998b), and in particular, the way in which it can be used to theorize curriculum, including the goals of curriculum. The second section explores the social realism of prominent sociologist Margaret Archer (1995). The third section discusses the social realist school within the sociology of education which is primarily concerned about the place of theoretical knowledge in curriculum (Young, 2008; Maton and Moore, 2010; Moore, 2013; Muller, 2000; Wheelahan, 2010). The final section discusses "transactional realism" (Biesta, 2014; Carlgren, 2020). This article provides an introduction into these different realist approaches, while it isn't able to enter into deep exploration about the debates between and within the different approaches. As with any substantive philosophy and social science, there is robust debate between and within these approaches and this is one way that knowledge develops and grows. The aim of this article is to provide a starting point for further investigation into these different realist approaches.

Critical realism

All social theories (such as social realism) are premised on a metaphysical premise about the nature of the world, society, and human agency. That is, our theory of ontology (what the world is like) shapes our theory of epistemology (the nature of, and how we gain access to, knowledge about the world) (Sayer, 2000). Sayer (2000, p. 78) explains that "Critical realism is a philosophy but its main focus is on ontology, not epistemology". There are three central propositions within critical realism: first, the real world exists independently of our knowledge of it; second, our knowledge of the real world is fallible; and third, there are grounds for judging some accounts as better than others (Bhaskar, 2008 [1975]). Critical realism is a materialist philosophy because it argues that our knowledge of the world arises from our practices in it. We find that things work or don't work, and we modify our understandings as a consequence. As we will see, things aren't quite so simple, but the notion of knowledge arising from practice is an important cornerstone.

Depth ontology: domains of the real, actual and empirical

Bhaskar (2011a, p. 146) explains that the world is “structured, differentiated and changing”. Planets, mountains, global warming, and Covid-19 exist, and so do societies, capitalism, nations, class, racism, misogyny, schools, and conspiracy theories. They exist regardless of whether we believe they exist. Critical realists argue that the natural and social worlds are complex and stratified. For example, Collier (1998b, p. 263) explains that:

Everything is governed by the laws of physics; since a few hundred million years ago, some of those but not all have been governed by the laws of biology; for a few hundred years, some but not all of those have been governed by the laws of capitalist economics, and so on.

This depth ontology allows critical realists to examine the interplay between different “levels” and objects (for example, the laws of physics, capitalist economics, factory production and strikes) (Collier, 1998b) to understand the emergent outcomes that ensue. Sayer (2000, p. 12) explains that critical realism is an emergent philosophy in positing that:

the world is characterized by emergence, that is situations in which the conjunction of two or more features or aspects gives rise to new phenomena, which have properties which are irreducible to those of their constituents, even though the latter are necessary for their existence.

This is in contrast to philosophies such as empiricism which is based on methodological individualism, in which the world consists of independent objects. The total is understood by adding up all the individual components and these components are not causally related. For example, Hume (1921 [1777], p. 27) who was one of the founders of British empiricism in the 1700s, in explaining how billiard balls move around the table, argued that “Motion in the second Billiard-ball is a quite distinct event from motion in the first; nor is there anything in the one to suggest the smallest hint of the other”. All we can know is that the billiard balls hit each other (something happened) and observe how often they hit each other. Similarly, while somewhat simplified, a “traditional” understanding of science is limited to observing and counting the constant conjunction of events—that something happened and how many times it happened.

Bhaskar developed critical realism in part in opposition to this reductionist account of science. He identifies three levels of reality in the natural and social worlds: the first is the domain of the real, which consists of structures and generative mechanisms. The second is the domain of the actual in which events take place. The third is the domain of the empirical in which experiences occur. This hierarchy and the relationship between each domain is presented in Table 1. Most of the time generative mechanisms are not observable, and we can only discern their effects in interacting with other generative mechanisms; for example, we can’t see gravity or class, but we can see their effects. Mechanisms interact with each other in open systems and this shapes the way they act, or sometimes, stops them from acting or changes the way that they act. For example, a virus will be stopped by a vaccine, or in the absence of a vaccine, its spread will be accelerated or slowed by the actions of communities and individuals (practicing social distancing or not, wearing masks or not). And, its effects will be shaped by relations of poverty and inequality. This example shows the difficulty of sharply distinguishing between the natural and social worlds, as does the problem of global warming (Benton and Craib, 2001).

The domain of the real shapes the domain of actual, in which events actually happen. Outcomes cannot be fully predicted in advance because events are always co-determined by multiple stratified structures and causal mechanisms (Collier, 1998b), as in the example of the spread of a virus. The extent to which events can be observed is an empirical one; for example, the development of microscopes allowed scientists to see viruses. The domain of the empirical is where we directly perceive events. For this to occur, events must have been generated by the interplay of mechanisms and structures. Empiricist philosophies focus on experiences and counting how many times they happen. According to Bhaskar (1998a), a focus on the “empirical world” to the exclusion of the actual and real reduces the ontological question of what exists to the epistemological question of what we can know or experience, and he refers to this as the “epistemic fallacy”. This is one reason why an over-reliance on large-scale data as the foundation of education research can lead to problematic conclusions about “what works” in practice. This depth ontology also allows us to understand absences, or why things do not happen, whereas counting the constant conjunction of events misses this.

Table 1 The domains of the real, actual and empirical.

Source: Bhaskar (2008 [1975], p. 2).

According to emergent philosophies such as critical realism, the total is always more than the sum of its parts. A society is more than the sum of the total number of people as it has its own properties, structures and mechanisms that affect people, and society in turn is affected by what people do. Bhaskar (1998c) explains that when people get up in the morning to go to work, their intention is not to reproduce capitalist economic relations, yet that is the outcome of their actions because they live and work in a capitalist society. Societies are structured by economies and by relations of power and domination, such as class, race and gender. Archer (2020, p. 141) explains that social structure, culture and human agency “are *different kinds of emergent entities* as is shown by the differences in their properties and powers, *despite* the fact that they are crucial for each other’s formation, continuation and development”. She illustrates this point about different properties by explaining that an education system may be centralized, but an individual cannot be centralized, while an individual can be reflexive, while an education system cannot.

Similarities and differences between the natural and social worlds

Bhaskar (1998b) argues that both the natural and social worlds can be studied scientifically, but that there are important differences between the two. Reality in both the natural and social worlds is stratified, complex and emergent, but the nature of the structures and objects in each differ even though they interact in emergent ways, as in the examples of a virus or global warming. First, social structures in the social world depend on human activity, unlike structures and mechanisms in the natural world (although this notion is challenged by global warming, at least to some extent). Consequently, social structures are only relatively enduring compared to the more enduring structures in the physical world. Social structures tend to change slowly as human activity changes and adapts to its environment, but they may be punctuated by revolutions or crises. An example of change is the change from feudalism to capitalism, and within capitalism, from the capitalist welfare state to the neoliberal market society (Harvey, 2007). One of Archer’s contributions is to theorize this process, and this is discussed in the next section.

The second difference is that the social world is, at least to some extent, concept dependent—it depends in part on the reasons and beliefs agents have, which help to shape their actions (for example, to wear a mask—or not—in the middle of a pandemic). An important part of understanding society is understanding meanings and beliefs, even if these meanings and beliefs are fallible (for example, that the Covid-19 disease is a conspiracy meant to destroy democracy). Sayer (2000, p. 17) explains that meaning can’t be counted, it can only be understood and this demonstrates the necessity for hermeneutical or interpretative research methods in the social sciences. While we may be able to count the number of people who believe that Covid-19 is a conspiracy and it may be important to do so, we need to understand why they think that. However, while beliefs may be a part of the social reality that we seek to explore, they do not explain everything about that social reality. It is also necessary to explore social structures, social institutions, and the way in which humankind engages with the natural, material and social worlds to reproduce and sustain itself.

Third, the social sciences have the capacity to react back on society and to help create change, for example, in providing insights into why different groups of young people drop out of school. Social science can offer alternative explanations to “common sense understandings” and this may help change social practices. Collier (1998a, p. 446) contrasts this to the natural sciences in explaining: “There can be no equivalent of this in the natural sciences. Black holes may be unpleasant things to contemplate, but that is no criticism of them. They exist—or don’t—and there’s an end of it”.

Bhaskar (2011b, p. 143) argues that the implications of critical realism for the aims of science (and social science) are not to seek control and prediction, but explanation, understanding and enlightenment. Control and prediction are possible in closed systems, but not in open systems, and the social world is by definition an open system because it comprises human agents. It may be possible to create a closed system to identify and “see” the actions of causal mechanisms in some sciences such as physics, biology or chemistry, where the possibility of controlling all variables exist. This is not possible in all natural sciences and it is impossible in the social sciences. This is because society is peopled by agents who act on their beliefs and reasons, and it is thus impossible to completely control all variables. Bhaskar (2011b, p. 144) explains that: “It follows from this that decisive test situations are in principle impossible; so that criteria for theory-choice and theory-development must be exclusively explanatory and non-predictive”. However, in contrast to relativist arguments that reduce theories to standpoints held by different actors so that theory is no more than an expression of power, Bhaskar argues that one needs to test theories empirically, which includes qualitative and quantitative research. (In critical realism, quantitative research in open systems does not require constant conjunctions of events or hypotheses testing.) Archer (1995, p. 23) explains that if we find the social world to be different from our conceptions as a consequence of our research, then we should modify our conceptions. There is an iterative relationship between our knowledge of the world and the way that the world is.

Intransitive domain (the natural and social world) and transitive domain (bodies of knowledge)

However, this relationship is imperfect, and our theories are not a mirror of the world (Scott, 2018). There is not a direct “correspondence” between our theories and the objects they describe. If this were the case, then knowledge would never change because it would always truthfully reflect the way the world is. Critical realists distinguish between the intransitive domain which refers to the “real” (the domains of the real, actual and empirical) in the natural and social worlds, and the transitive domain which refers to our knowledge of the real, or in other words, our knowledge of the natural and social worlds. It is this distinction that allows critical realists to distinguish between a realist ontology (the real world exists), fallible knowledge or epistemology (we might be wrong), and judgmental rationality (some theories work better than others, because we’ve checked) (Collier, 1994). According to this

approach, our theoretical knowledge reflects our best efforts so far in understanding the natural and social worlds, but that our knowledge will develop as we gain better understandings through our research and practice in the world.

Objects and structures on the one hand, and our knowledge of objects and structures on the other, are not the same and each has different properties. Our knowledge of the world is always concept-dependent, and these concepts will in part shape what we see and how we understand what we see. This is why our knowledge will always be fallible and provisional, because our experience in the world is always shaped by our theories, but it is not determined by theories (Sayer, 1992). We “see” the world through our conceptual lenses. For example, two teachers, each with contrasting understandings about class and disadvantage, may view the same group of students differently and respond to them differently.

The conditions that are needed to build theoretical knowledge are not the same as the referents (objects) of that knowledge. While black holes and societies exist, their existence doesn’t rely on what we know about them. Societies may change as a result of theoretical knowledge, but this process is usually slow and protracted, and only occasionally punctuated by revolutions and crises. Bhaskar (1998b, p. 34) explains that the raw materials used in constructing new theories in science “include established results and half-forgotten ideas, the stock of available paradigms and models, methods and techniques of enquiry ...” Once codified, theoretical knowledge has properties of its own that can’t be reduced to the conditions of its production or the standpoint of those who produced it. This is for two reasons. The first is that this knowledge is about something, and not just the perceptions or standpoint of those who developed that knowledge. The second reason is, as Chalmers (1999) explains, because theories have properties that are independent of their knowledge producers, they may have implications about which the original knowledge producers are unaware. People build new knowledge using (accepting, extending, modifying, transforming, rejecting) knowledge that went before. Bhaskar (1998b, p. 34) explains that “the scientific innovator comes to appear in retrospect as a kind of cognitive bricoleur”.

This distinction between the intransitive and transitive dimension allows us to understand that each may change independently of the other. For example, the objects of knowledge may undergo a fundamental change, while theoretical knowledge hasn’t caught up; or, theoretical knowledge may develop and change toward a better understanding of its object. This is one reason why we can never definitively say we have arrived at the “truth”, even though we may be getting closer to it.

Knowledge of the powerful and powerful knowledge

Knowledge depends on social communities for its production. Creating knowledge requires “institutional structures and cultures to support develop, codify, curate and transmit knowledge” (Wheelahan, 2014, p. 128). The academic disciplines provide the main framework for developing knowledge, although they are not the only way such knowledge is created. The disciplines have rules for creating, codifying and testing knowledge which are fallible, but the best tools we have to date. Universities are the main institutions which have provided the academic disciplines with a home, and in the Western world both universities and the disciplines have changed since the founding of the University of Bologna in 1088 (see Hayhoe, 2005, 2019 for a discussion of the historical development of scholarly institutions in other civilizations). This elaboration of institutions of knowledge production in turn reflects the growth and complexity in society, and requirements for an increasingly complex and interdependent division of labor in society (Bernstein, 2000).

Because knowledge is produced socially, it bears the marks of those who have produced it. The academic disciplines in universities have historically been dominated by social elites, and the production of knowledge bears these marks, including racism, sexism, homophobia, colonialism, class and other relations of domination and subordination. And historically, those who suffer the deleterious effects of these relations of domination have had to fight for access to universities and other sites of knowledge production, just as they have had to do in every other social institution in society. These struggles have resulted in the establishment of new disciplines such as women’s studies, Black studies, and cultural studies in the latter part of the 20th Century, and the challenging of these relations of domination and subordination within existing disciplines such as medicine, education, engineering, history, economics and philosophy. These challenges have only been partially successful and will always only be partially successful because universities reflect, even if they sometimes challenge and help to change (at least a little bit), society’s relations of power and social structures.

Even though theoretical knowledge will always reflect relations of power, this doesn’t mean that such knowledge is reducible to power. This is because such knowledge is *about* something *other* than relations of power. Theoretical knowledge is powerful because it provides at least some epistemic access to the natural and social worlds, even if this access is imperfect, fallible and shaped in part by relations of power. Michael Young (2013), a leading scholar within the social realist school in the sociology of education, distinguishes between powerful knowledge and knowledge of the powerful. Powerful knowledge is powerful because it provides (at least some) epistemic access to its objects in the natural and social worlds. On the other hand, knowledge of the powerful is shaped and distinguished by unequal social access to knowledge production, acquisition and use. The social elites seek to ensure their privileged access to theoretical knowledge precisely because of the way it can be used in society and the economy—because of its power in understanding the natural and social worlds.

Implications of critical realism for curriculum

There are several implications of a critical realist analysis for curriculum. The first is that knowledge and knowing are not the same. Theoretical knowledge is codified knowledge embedded in relational systems of meaning. Each academic discipline is a body of

abstract knowledge about its object. No academic discipline can represent the world in its entirety, and can only ever have as its referent a small slice of “the real” (Collier, 1997). The task of curriculum is to help students enter different system of meaning and make sense of them. Students are apprentices at different stages of their journey who need to learn their theoretical tools of the trade. They need to make sense of these tools, engage with them skillfully and critically and perhaps contribute to their evolution, but the main point is to help students learn to use these tools to enter and move around within systems of meaning, and to apply knowledge in contextually specific and appropriate ways.

The second implication is that seeking truth about an objective natural and social world should be a normative goal of curriculum even if our knowledge is always partial and revisable, and marked by the social conditions under which it was produced. The objectivity of knowledge is an important principle for curriculum, but as discussed earlier, this is not based on a “correspondence theory” of truth where knowledge directly reflects its objects. Collier (2003) explains that the objectivity of knowledge can be understood in three ways: first, that something exists independently of our knowledge and/or awareness of it. The earth has always been round, even when most of the world’s population thought it was flat. The second meaning of objectivity concerns the nature of human judgments. Knowledge is objective (but still fallible) if it is caused by its object, and not, as Collier (2003, p. 135) explains “by some feature of its subject other than that subject’s openness to the effects of the object”. That is, such knowledge, even if it is imperfect, is about something external and not just a reflection of our internal state. Collier explains that the third meaning of objectivity is objectivity as a human attitude. We seek knowledge (the second meaning of objectivity) about an independent reality (the first meaning of objectivity). So, as a consequence of this third meaning of objectivity, we need to develop the means and tools to seek such knowledge, develop criteria that we use to judge knowledge claims, and be open to the possibility that we are wrong. Otherwise, as Collier (2003, p. 137) explains: “the alternative is to be shut up in one’s own subjectivity”. These three dimensions of objectivity demonstrate why and how knowledge may be fallible and revisable, but still objective.

The third implication for curriculum is that students need to understand how knowledge is produced in different fields and to gain access to the criteria needed to judge knowledge claims. This goes far beyond teaching students propositional “know that” knowledge as truth. Winch (2013, p. 130) explains that propositional knowledge is “embedded within a conceptual structure which is itself embodied in further related propositions”. Students need access to this relational conceptual structure within bodies of knowledge, to their inferential relationships, and to the procedures used to make these claims and to evaluate them. This is not an argument for “the canon as truth”. This is an argument for inducting students into a critical stance within bodies of knowledge where they engage with the criteria used to judge existing and new knowledge. This treats knowledge as objective knowledge yet socially produced and fallible, but about which judgments can be made. The aim is to give students the epistemic tools they need to gain access to the social and natural worlds, and to participate in debates about what our society should be like.

Critical realism provides a foundation for thinking about the nature of curriculum (Priestley, 2011; Scott, 2000, 2014), but it doesn’t provide all the answers. It provides a philosophical foundation, and as such cannot do all the work that is needed to theorize the nature of curriculum. Critical realism under-labours the social sciences by providing a realist framework for complementary social theories that explore society. Bhaskar (1998b, p. 5) explains that philosophy can tell us that the world is stratified, but “it cannot tell us *what* structures the world contains or *how* they differ”. Archer (1995, p. 22) explains that ontology “acts as both gate-keeper and bouncer for methodology”. For example, theories premised on methodological individualism are ruled out, while those based on an emergentist and realist philosophy are in play (see Archer, 2020). This leaves considerable scope for debate within emergentist realist social theories such as Archer’s and the social realist school within the sociology of education.

Archer’s morphogenetic social realism

Margaret Archer’s (1995, 2000a) morphogenetic realist social theory builds on critical realism and it has become very influential in sociology. Her approach theorizes the relationship between the individual and the social, with both premised on a materialist and emergentist ontology. She uses “analytical dualism” to distinguish between agency and social structure, arguing that each has different emergent properties, and that neither is reducible to the other. For example, a society can have a young or old demographic structure, be more or less unequal, and have different types of political systems and economies. In contrast, individuals have capacities for cognition, perception and consciousness, and reflection.

Archer insists that in analytically distinguishing between agency and structure she avoids under-socialized accounts of the individual based on methodological individualism in which society is the sum total of individuals scurrying about their business. Such approaches are guilty of “upwards conflation”. She also avoids “downwards conflation” in which personhood is the gift of society with the individual who is discursively constructed in society which, she argues, results in the over-socialized individual (for example, that an individual is nothing more than a product of their culture or religion). And, she avoids the problem of “central conflation” which she attributes to Giddens (1984) in his theory of structuration. Giddens defines social structure as rules and resources that individuals draw upon in acting and in the process they “instantiate” social structure. Archer (2010b) critiques this approach for collapsing the distinction between structure and agency, for collapsing the temporal dimension between actions of agents and social structure, and for excessive voluntarism (all that is needed for social change to occur is for individuals to change what they do).

Archer (1995) explains that while society emerges from social relations between agents (and their interactions with the natural and material worlds), it is not possible to add up all individuals in society to explain what a society is. A society would not exist without agency and is thus activity dependent, but it has emergent properties which mean that it is not reducible to agency and is able to act back on agency. For example, a society with high unemployment is also likely to be highly unequal and to deny opportunities to young people which may well shape their life chances. And relations of patriarchy and racism are also real and shape the life chances of individuals. Gorski (2017, p. 34) explains that the consequence of this depth ontology is that “human persons and societies may have certain latent potentials whose development has been suppressed and whose absence manifests in ill-being”.

The temporal dimension is very important in Archer’s approach. She explains that structure predates human activity; that is, social structures are the outcomes of past agential activity and they provide the parameters that individuals act within in the present. She argues that social structures condition human agency but do not determine what individuals will do precisely because they are agential beings. The outcome of social interactions by agents within existing social structures determines whether no change occurs (morphostasis), or whether social change occurs (morphogenesis). This is why her approach is called the morphogenetic approach.

Her analysis of the nature of the individual is a key component of her approach, and she insists on the ontological status and irreducibility of the self (Archer, 2000a). Archer (1995) draws on the seminal work of Marcel Mauss ([1938] 1985) (French scholar and Emile Durkheim’s nephew) to argue that the sense of self is universal, while the concept of the self is historically and socially situated. This helps us to see that the conception of the self of Western individualism is a socially, temporally and historically specific construction, while not denying that there are selves. That is, there is an enduring “self” who has continuity even though this self may change in engaging with the natural, practical and social worlds, and over time in engaging with others in socially conditioned circumstances (which includes relations of class, gender and race). This self has a past, present and a future and acts reflexively in responding to the situation in which they find themselves, which may result in the emergence of new identities and subjectivities (Clegg, 2006).

Archer (2003) refers to the internal reflexivity that all individuals engage in as the “internal conversation”. We reflect, consider, make decisions, change our minds and act in engaging in the social, practical and natural worlds. This resonates with Bhaskar’s (1998b) insistence that our knowledge of the world arises from our practice in the world. Archer provides insight into the iterative relationship between our inner conversation and our practice in the world. She argues that the self is defined by things that matter to us, including who and how we choose to love, our priorities and where we choose to “invest” ourselves, even this results in detrimental outcomes for ourselves. Collier (1999) argues that our emotions are our internal commentary on the things that matter to us, and consequently emotions are not irrational, although they are fallible if our understanding of the situation in which we find ourselves is mistaken. Our “inner conversation” mediates our relationship with the world and is not purely self-referential (Archer, 2000a, 2003). While agreeing with Archer about the irreducibility of the self, Archer’s account of the inner conversation is arguably over-intellectualized in discounting the ways in which our experiences acquired over a lifetime are inscribed in our “habitus” and help to orient our understandings of the normal, natural and taken-for-granted (see the debate between Sayer, 2010, and Archer, 2010a).

Archer’s work has been used in theorizing about pedagogy (particularly teaching and learning in post-secondary education) (see Case, 2015, 2017; Clegg, 2005, 2006; Ashwin, 2012), but there has been less work that considers the implications of her work for curriculum (but see Priestley, 2011; Maton, 2014; Wheelahan, 2007). Regardless of any reservations, Archer’s is an expansive notion of human agency which stands in stark contrast to the homo economicus (Devas, 1883, p. 27) of human capital theory (Archer, 2000b). This is the notion of the human agent which underpins curriculum in which the purpose of education is reduced to preparing people for work. This is why Archer’s approach has implications for theorizing curriculum and not just pedagogy because the purposes of a curriculum are more expansive based on a more expansive notion of the agent. Her notion of investment encompasses all the things that matter to us, and not the instrumental self-maximizing economically “rational” self whose main goal in life is realization of their market selves.

The social realist school in the sociology of education

The main focus of the social realist school within the sociology of education is on theorizing the role of theoretical knowledge in curriculum (Young, 2008; Muller, 2000; Moore, 2004; Maton and Moore, 2010; Maton, 2014; Wheelahan, 2010). All those within the social realist school acknowledge their debt to the British sociologist Basil Bernstein who was an English sociologist of education from the 1960s until the end of the 20th century (see Muller and Gamble, 2010). Bernstein (2000) in turn, acknowledges his debt to Durkheim who was a founder of the discipline of sociology in the 19th century, as do all within the social realist school. However, not all those within the social realist school draw on critical realism, or draw on critical realism as markedly as does this article even though all are committed to a realist ontology (Young and Muller, 2007).

As part of his oeuvre, Bernstein theorizes the nature of, and structures of, theoretical knowledge and everyday knowledge, and in doing so he addresses a key shortcoming in critical realist theorizing about the nature of knowledge. If the transitive domain is relatively independent of the intransitive domain and has its own properties, then we should seek to theorize those properties. There hasn’t been a great deal of critical realist work within the sociology of education that takes on this task. Knowledge is mostly taken as a given (for exceptions, see Scott, 2010; Wheelahan, 2010; Maton, 2014). From Bernstein (and before him, Durkheim), social realists insist on the distinction between theoretical knowledge on the one hand, and everyday knowledge on the other, arguing that each has different properties and that this has implications for structuring curriculum.

Bernstein's approach is fundamentally Durkheimian because of his analysis of the nature of knowledge. Bernstein shares with Durkheim the view that all societies distinguish between esoteric knowledge on the one hand and mundane knowledge on the other (Bernstein, 2000; Durkheim, 1967). Esoteric knowledge is theoretical and conceptual knowledge, while mundane knowledge is "every day" common sense knowledge (Bernstein, 2000, p. 157). Bernstein argues that the distinction between the two is universal, while the content of each is culturally and historically specific. It is the fact of this distinction, and the social relations underpinning it, that shapes the social division of labor and knowledge production, rather than the relationship between knowledge and the object that knowledge is about.

This is an idealist ontology that makes primary the ideas that humans use to make sense of their world and make their way in the world (Johnson et al., 1984). Or as Bernstein (2000, p. 82) says, "Word before the World". In contrast, critical realism is a materialist ontology because its premise is that knowledge arises from our practice in the world. Or, world before word. However, Bernstein and Durkheim are realist because they regard the social structures that arise from the ideational division of labor as real structures that are not reducible to the individuals that comprise a society (Bernstein, 2000; Durkheim, [1897] 1951). Durkheimian approaches are thus idealist and realist—the real is the ideal, and because it is real, knowledge has objective qualities and is not relativist (although still fallible). However, arguably, as well as being realist, Durkheim's approach is also emergentist (Sawyer, 2002). Durkheim ([1897] 1951, p. xxxvi) argues, for example, that "It is not realized that there can be no sociology unless societies exist, and that societies cannot exist if there are only individuals". Moore (2006) argues that even though Bernstein eschewed labels, that Bernstein's approach is nonetheless best understood as a form of critical realism because of his realist and emergentist emphasis, and because of his insistence that theory describe something external to itself; theory needs to describe and explain practices, processes, structures and outcomes and their inner logics.

Social justice and social and epistemic access to knowledge

Bernstein is fundamentally concerned with social justice and distributive justice. He argues that access to theoretical knowledge provides the grounds for democracy. Theoretical knowledge is the means through which society conducts its conversation about itself, and debates what it should be like in the future. It provides the knowledge that society needs to consider alternative futures, such as ameliorating global warming or responding to the refugee crisis. It is fallible and marked by social elites, but it is society's best efforts so far. He argues that individuals have the "right to the means of critical understanding and to new possibilities", the right to be "included socially, intellectually, culturally and personally", and, "the right to participate" (Bernstein, 2000, p. xx). Access to knowledge is a key precondition for participation. Young (2010, p. 6) explains that consequently the purpose of education is to provide students with access to the knowledge that "takes them *beyond their experience* and which they would be unlikely to have access to at home, at work or in the community". This is a precondition for all students to be able to participate in debates about what society should be like and in debates and controversies within their occupation. Bernstein shows that there can be no social access to theoretical knowledge without epistemic access, and his life's work was to demonstrate how working class students were systematically denied this access through the structuring of knowledge in the curriculum.

Bernstein's main focus was on theorizing the nature of curriculum and how the "pedagogic device" mediates access to theoretical knowledge. He explains how distributive, recontextualizing and evaluative rules mediate access to pedagogic codes (how knowledge is classified into different domains and how it is framed, paced and sequenced), and how the construction and structure of these codes either obscures or facilitates students' access to theoretical knowledge (Muller and Gamble, 2010; Singh, 2002). While this is so, the pedagogic codes used in school that draw on abstract and conceptual knowledge (and arguably, in college and university) are more congruent with those used in middle class homes, with the latter providing "an effective second site of acquisition" (Arnot and Reay, 2004, p. 204). Middle class students are thus doubly privileged as the curriculum they engage in at school provides them with privileged access to theoretical knowledge, while the curriculum for students from working class backgrounds is more likely "to stress operations, local skills rather than the exploration of principles and general skills, and the pacing is likely to be weakened" (Bernstein, 2003, p. 77).

Horizontal and vertical discourses

Bernstein (1999, p. 157) explains that it wasn't until relatively late in his career that he turned his attention from a "theory of the construction of pedagogic discourse" to theorizing the nature of theoretical and everyday knowledge, their structures and "the internal principles of their construction and social base". This was to become a fundamental and enduring part of his work. He describes everyday knowledge as "horizontal discourse" and theoretical knowledge as "vertical discourse", with each having different rules for its generation and acquisition. Horizontal discourse is "common-sense", everyday knowledge which is "likely to be oral, local, context dependent and specific, tacit, multi-layered, and contradictory across but not within contexts" (Bernstein, 1999, p. 159). Vertical discourse, in contrast, consists of "specialized symbolic structures of explicit knowledge" (p. 161) that "takes the form of a coherent, explicit, and systematically principled structure" (Bernstein, 1999, p. 159).

Within vertical discourses, Bernstein distinguishes between the sciences which are hierarchically organized (for example, physics), and the social sciences and humanities which "take the form of a series of specialized languages". An example of a discipline with multiple languages is sociology, which comprises competing paradigms which include, among others, conflict theory and functionalism. Bernstein calls the pure academic disciplines "singularity" because they face inwards to a single knowledge

structure, while he calls applied disciplines “regions”, because they sit at the interface between the pure disciplines and the occupational field of practice, and they integrate and recontextualize knowledge from the “pure” disciplines for the field of practice. The pure and applied academic disciplines have authoritative speakers, principles and rules for generating new knowledge, and criteria for judging knowledge claims. Students need access to the principles for constructing the discipline or applied discipline (its key concerns and how they are distinguished from other disciplines and fields) and knowledge building, and for evaluating knowledge claims. They also need to be inducted into debates and controversies within the disciplines. Hierarchically structured disciplines (such as physics) must ensure that students can understand what comes first before they can understand what comes second, and the social sciences and humanities must ensure students understand the different languages, speakers and authoritative texts (Muller, 2009).

As with Bernstein’s work (Muller and Gamble, 2010), there are debates about, on the one hand, the extent to which social realism is indeed seeking to induct students into the conservative “authoritative cannon” with rigid and untouchable boundaries, and in which the voice of authority provides the grounds for belief, thus legitimating the cultural domination of elites. And, on the other, whether it is a progressive argument designed to support students’ social and epistemic access to knowledge that is emergent, fallible, and revisable based on a critical stance in which students are provided with access to the criteria for judging knowledge claims (Young and Muller, 2010, 2013; Muller and Young, 2019; Morgan et al., 2019).

This is why Young’s (2009) explanation of the distinction between, but also the relationship between, powerful knowledge and knowledge of the powerful is important (Muller and Young, 2019; Beck, 2018). Each has a different kind of power; powerful knowledge provides social and epistemic access to knowledge needed to understand and navigate one’s way in the world. This is potentially available to all, but access to it is restricted by relations of power and domination, in which social elites dominate access to knowledge by dominating access to elite schooling and elite curriculum, and then to elite universities and elite professions. This is knowledge of the powerful. Social elites also have a relative monopoly over the production of such knowledge, and knowledge produced by social elites will reflect these conditions of its production. This is another reason why democratic access to knowledge is so important. However, it is not just democratic access to knowledge that is important, it is also democratic access to knowledge production that is important.

Transactional realism

Like Bernstein, the famous, influential and long-lived United States philosopher and psychologist John Dewey (1859–1952) was concerned with democracy and social justice (see Dewey, 1997 [1916]). He was a founder of pragmatism within both disciplines (Hildebrand, 2018). Hildebrand (2018, p. 1) argues that Dewey was “arguably the most prominent American intellectual for the first half of the twentieth century”. And, arguably, his book *Democracy and Education* is still of fundamental importance in thinking about the aims of education (Dewey, 1997 [1916]). Dewey’s work provides the basis for “transactional realism” and this has been elaborated in the philosophy and sociology of education by scholars such as Biesta (2014, 2020), Carlgren (2020), and Wahlström (2020a,b) (see also Garrison, 1994).

Dewey’s pragmatism emphasizes processes of knowledge creation and meaning-making in which education is a “continuous reconstruction of experience” (Dewey, 1997 [1916], p. 80). The emphasis is experiential, which means that the contextual and situated takes priority. However, Dewey is clearly not a relativist. His insistence on the scientific method of inquiry demonstrates his belief that the external world is not purely a social construction brought about by acts of signification (Dewey, 1997 [1910], p. 27). Biesta (2020, p. 96) explains that “we live ... in a real world, not a fantasy” and we “encounter this reality when our initiatives meet resistance” in the material and social world. Biesta (2014) explains that Dewey’s theory of education is communication-centered, which emphasizes the connection—or the transaction—between the student and the curriculum in the case of education, or between experience of “living organisms” and the environment more broadly. It is realist because not just any connection is possible, as a consequence of butting up against the world. Biesta also problematizes the “learnification” of education, in which the emphasis moves away from education to learning (Biesta, 2009, 2014). Learnification results in “the translation of everything there is to say about education in terms of learning and learners” (Biesta, 2009, p. 38). This ignores the fact that students “learn something, that they learn it for a reason, and that they learn it from someone” (Biesta, 2020, p. 91).

However, arguably, Dewey (1997 [1916], p. 339) collapses the distinction between knowledge and knowing by focusing on the contextual in arguing that: “knowledge is a perception of those connections of an object which determine its applicability in a given situation.” Moreover, the action oriented nature of knowing so that knowing is “in action” lends itself to a “what works” or a pragmatist criterion for evaluating knowledge. Biesta (2014, p. 39) cites Dewey in saying that “The question of truth is not as to whether Being or Non-Being, Reality or mere Appearance is experienced, but as to the *worth* of a certain concretely experienced thing”. In this way, Dewey arguably ends up at subjectivism or more charitably at an intersubjective world (see Biesta, 2014, p. 43 for a discussion of this point). Biesta (2014, p. 45) explains that “the most important question to ask from the point of view of pragmatism is not ‘What is true?’ but ‘What is the problem?’” From a critical realist perspective, Sayer (2000, p. 42) explains that “The question is not only what works, but what is it about the world which makes it work”. A pragmatist “what works” from the perspective of a particular problem doesn’t necessarily provide insights into the structures and mechanisms of the real, and consequently, knowledge derived in this way may “work” but still be wrong in important respects (Chalmers, 1999).

Dewey is not relativist about the world, but he is arguably relativist about knowledge. Moreover, his realism about the world is very attenuated. Biesta (2014, p. 40) explains that:

Dewey's approach also has implications for how we understand the objects of knowledge. Whereas in the dualistic approach the objects of knowledge are seen as "things" that exist in a world "out there" and are there for us to discover and depict, Dewey's transactional view sees the objects of knowledge as the *outcomes* of processes of inquiry.

This is a quite distinct approach to critical realism which distinguishes between the intransitive and transitive domains, with each having different conditions necessary for their existence. Experience, while a precondition for knowledge, is not sufficient if that knowledge is to be codified, elaborated, and institutionalized in an elaborated system of meaning.

It is important to distinguish between curriculum and the production of knowledge in the academic disciplines. It is possible to agree with Carlgren (2020, p. 332), a proponent of transactional realism, who argues that "the aim of education is to produce knowledgeable people" and that this is a precondition for democracy (Wahlström, 2020a,b). However, the production of knowledge and the curriculum have different aims, dynamics and conditions for their realization. The structures of knowledge do have implications for curriculum depending on whether they are hierarchically structured or structured as horizontal languages (Muller, 2009). Students must engage experientially with the objects of these knowledge structures, as well as engaging with the relational system of meaning about those objects of knowledge. The challenge for a curriculum is to work out how that should be done for different groups of students at different stages of development who are studying different sorts of programs for different purposes at different types of institutions (schools, colleges and universities). Finally, one can agree with Russell (1945, p. 819) who explains that while he greatly admires Dewey and that he wishes that he could "agree completely" with him, but that

... to my regret I am compelled to dissent from his most distinctive philosophical doctrine, namely the substitution of "inquiry" for "truth" as the fundamental concept of logic and theory of knowledge.

Conclusion

Realist approaches have implications for theorizing the aims and purposes of curriculum, and also for what should be included in curriculum. The purpose of curriculum is to produce "knowledgeable people" (Carlgren, 2020) about the world, a real world which is stratified, complex and emergent (Bhaskar, 1998b). This is based on an expansive view of the human actor, their motivation and concerns and the complexity of their worlds, and not the homo economicus "man" of human capital theory (Archer, 1995). We want students to be able to participate in debates and controversies in society about what our world should be like, and to participate in and shape debates and conversations about their occupation (Bernstein, 2000). Theoretical knowledge is powerful knowledge, and students require epistemic access to this knowledge, as a precondition for social access. We need to distinguish between powerful knowledge and knowledge of the powerful if we are to provide students with access to the former, while challenging relations of power intrinsic to the latter (Young, 2013). The structures of knowledge as either hierarchical or multiple languages has important implications for curriculum and for curriculum coherence (Muller, 2009). The aim is to ensure students have access to the way knowledge is built, and to the criteria for judging knowledge claims, which is a critical position that rejects the canon as authority and truth. The curriculum needs to be based on the normative principle of seeking truth about a real world, while recognizing that our knowledge of that world is fallible, but about which we can still make judgments (Collier, 2003).

Introduction

World-systems analysis (WSA) is an ongoing intellectual movement that [Wallerstein \(2001\)](#) described as “a critique of existing dominant views in the various social sciences, and primary of developmentalism and modernization theory ...” (p. 266). The WSA project has been wide-ranging in its scope and ambition, promoting academic work with explicit commitments to the construction of a world-system that is more equal, just, and democratic than our current, historical, capitalist world-economy. As a knowledge movement in the social sciences, WSA elaborated an approach of “historical social science” that challenged institutional boundaries between disciplines and the established structures of knowledge within them. Historical social science brought together the nomothetic pursuit of universal and generalizable truth and particular, idiographic, conceptions of the good, in an effort to “construct understandings of reality that, albeit inherently approximate and certainly not deterministic, will be useful heuristically in focusing us on the historical options we have in the present in which we all live” ([Wallerstein, 2004a](#), p. 3).

This statement from [Wallerstein's \(2004a\)](#) introduction to *The uncertainties of knowledge*, expresses an important feature of the WSA project, with implications for the question of curriculum theorizing and contents. The project explicitly invokes ideas of the “usefulness” of knowledge generated by world-systems analysis, as criteria for assessing its worth. Usefulness is marked in terms of what Wallerstein identifies as three key tasks of WSA: the intellectual task of understanding social reality; the moral task of imagining alternatives; and the political task of taking action to transform our reality. In WSA terms this involves developing our understanding of the origins and historical trajectory of our existing world-system, as the primary unit of analysis of social reality, locating analyses of present reality within these terms, and engaging in the “utopistics” project of the

sober, rational, and realistic evaluation of human social systems, the constraints on what they can be, and the zones open to human creativity. Not the face of the perfect (and inevitable) future, but the face of an alternative, credibly better, and historically possible (but far from certain) future.

[Wallerstein \(1998, p. 2\).](#)

As articulated by [Wallerstein \(2012\)](#), if world-systems analysis “ends up as being merely one more theoretical position within the social sciences, it will have failed in what it had hoped to accomplish” (p. 521). What did it hope to accomplish? According to [Wallerstein \(2012\)](#), the ambition was unambiguously focused on a “rejection of the entire framework of mainstream social science,” leading to its “unidisciplinary reorganization” (p. 520). The reorganization rejected the divisions of knowledge across economics, politics, and socio-cultural areas of analysis, insisting that all three are “intrinsically linked” and “define each other” (p. 518). Crucially, given some critiques of the Marxist and so-called economic determinist character of WSA, Wallerstein stressed that none of these intrinsically linked areas is “primary,” hence the emphasis on an unidisciplinarity.

Structures of knowledge

WSA operates with a conceptual framework involving the notion of historical social system (including a typology of systems) and a systematic view of the capitalist world-economy with its structural (core–semiperiphery–periphery), temporal (cyclical and secular) and political (hegemony, ideologies, antisystemic movements) dynamics. WSA also encourages epistemological reflection on the social sciences. This reflection was undertaken by Wallerstein and the Gulbenkian Commission on the Restructuring of the Social Sciences, and the Fernand Braudel Center's working groups, such as the Structures of Knowledge Research Working Group, the Categories of Social Knowledge RWG and RWG on Methodology across the Disciplines ([Report, nd](#); [Wallerstein, 1996](#)).

Wallerstein's critique of the historical shaping of social science(s), and the "two cultures" rift within and between the social sciences and humanities was a constant theme in his writings. A collection of essays published between 1982 and 1991 (Wallerstein, 2001) was presented as a call to overcome "the limits of 19th-century paradigms" and set out the task to "unthink" the prevailing assumptions. As Wallerstein (2001, p. 1) explained:

I have entitled this book, "unthinking social science" and not "rethinking social science." It is quite normal for scholars and scientists to rethink issues. When important new evidence undermines old theories and predictions do not hold, we are pressed to rethink our premises. In that sense, much of nineteenth-century social science, in the form of specific hypotheses, is constantly being rethought. But, in addition to rethinking, which is "normal," I believe we need to "unthink" nineteenth-century social science, because many of its presumptions—which in my view are misleading and constructive—still have far too strong a hold on our mentalities. These presumptions, once considered liberating of the spirit, serve today as the central intellectual barrier to useful analysis.

Wallerstein suggested six themes, where this task of "unthinking" social science knowledge can lead to its fruitful reconstruction. The first theme is the critical understanding of the invention of the social sciences as a feature of the historical dynamics of the modern world-system. This centers around the question of how and why the social sciences emerged and became institutionalized in the 19th century as separate disciplines to study the past and the present; the state, the market, and the society; the "West" and the "rest." These "cleavages" were associated with the disciplines of history, political science, economics, sociology, social/cultural anthropology, and oriental studies, that eventually split into social sciences "proper" and humanities. The social sciences were also caught up in the epistemological division described by Wallerstein (2001) as "the false nomothetic-idiographic antinomy" (p. 2), whereby the natural sciences applied a nomothetic epistemology to produce universal truths, while philosophy and the humanities involved idiographic projects focused on particular descriptions social phenomena. A consequence was the reinforcement of the divide between work in pursuit of the truth and that in pursuit of the good.

The second theme focuses on the notion of *development*, presented as "the key, and most questionable, concept of 19th-century social science" (Wallerstein, 2001, p. 2). Wallerstein assumes the need for the critical understanding of the concept's centrality not only in the later part of the 20th century, where it served to capture disparities between core and periphery in the capitalist world-economy, but as "an avatar of the concept of an 'industrial revolution' ... and ... the axis not only of most historiography but of all the varieties of nomothetic analysis" (Wallerstein, 2001, p. 2). As such, the concept has been only partially correct and rather than an accurate heuristic device it served as an ideological signpost for major political camps (from pro-capitalist conservatives to liberals to socialists and communists). The concept led to "false expectations," like earlier theories of social evolution, and to overlooking the actual unequal interconnectedness of core and peripheral zones of the world-economy. Importantly for WSA, by failing to account for the relational aspect of the world-system, development-oriented scholarship privileged the nation-state as a unit of comparative analysis, whereas WSA points to the *world-system* as the more adequate level to explore global economic (axial division of labor) and political (hegemony) distribution of power. In other words, WSA postulates that rather than tracing development of a nation-state society we should examine the expansion of and transformations within the capitalist world-economy, processes that result in underdevelopment as much as growth, and that the relation-ality of core-periphery dynamics is an analytical key to this.

The third theme is a call to problematize the often neglected notions of time and space. Wallerstein (2001) suggests that "one of the most remarkable achievements of the epistemology that has dominated social science has been to eliminate TimeSpace from the analysis," (pp. 2–3) even though geographic and temporal considerations remained prominent in social research. Rather than fixed, stable, and eternally universal, TimeSpace in human history should be seen as a social creation, and furthermore this concept can help distinguish between different levels of historical analysis. Here WSA draws on Braudel's (1982) conceptualization, which points to different time-spans and to objects of measurement associated with them (Wallerstein, 2001, p. 136). Braudel proposed three subcategories of these time-spans: history of events (*l'histoire événementielle*), cyclical history (*l'histoire conjoncturelle*) and structural history (*l'histoire structurelle*). It is mostly on the first level—that of events, episodes, and directly observable short-term processes—that a vast part of traditional historical studies operated. Wallerstein (2001, pp. 139–144) argues that each of these categories of time, or time-span, is associated with certain space thus forming different TimeSpace realities: geopolitical timespace associated with the history of events, or episodic time; ideological timespace associated with cycles (the Cold War "East-West" or later "North-South" divisions can serve as examples here); and world-system, that is, capitalist world-economy, timespace associated with structural or long-term history (*longue durée*). Wallerstein also introduces the concept of TimeSpace of human choice, based on Tillich's (1948) distinction between "quantitative" and "qualitative" time, that is, between *chronos* and *kairos*, or "formal time" and the "right time," and this transformational TimeSpace is perhaps best signified by terms such as "crisis" or "transition" (Wallerstein, 2001, p. 146). The notion of transformational TimeSpace opens up the question of systemic change. Historical social systems persist over long periods as structural TimeSpace, yet the "tension between cyclical rhythms and the secular trends" (Wallerstein, 2001) is where mid-term and long-term changes occur, and they can be understood deterministically rather than otherwise. However, when the system faces its structural crisis, the time of transformation makes human beings face moral choice concerning the future. *Kairos*

is the TimeSpace of human choice. It is the rare moment when free will is possible. ... Human beings therefore, faced with *kairos*, faced with what I shall term transformational TimeSpace, cannot avoid moral choice. It is thrust upon them, at the "right" time and space, at a moment of qualitative time and space whose length and breadth are of uncertain and unpredictable locus. But despite all these uncontrollable elements, we can be certain that there is a *kairos*, a TimeSpace at which transformation does occur, a TimeSpace in which we all exercise our free will for good or ill. And when it comes, we choose our new order.

Wallerstein (2001, p. 147).

It is this aspect of human choice at the time of a systemic crisis, or "bifurcation," that pertains to Wallerstein's concept of *utopistics*, that is, a reflection on possibilities and directions of action for change.

Wallerstein's reading of Braudel also underpins the fourth major theme in his effort of "unthinking" social science. Braudel advocated interdisciplinary cooperation in defining common themes and directions of inquiry. He saw the plurality of social time and long-term perspective as having a particular value for such efforts. Moreover, Braudel's approach to economic history provides an important angle for WSA, namely his distinction between capitalism and the market. The distinction rests on a long-term view that profit-oriented exchange, i.e., markets, pre-dated the capitalist world-economy. Wallerstein (2001, p. 207) echoes Braudel's claims that contrary to dominant views of liberals and most Marxists, capitalism is effectively anti-market. The reading of Braudel also inspires a critical scrutiny of the common-sense view that positions the market against the state. Wallerstein (2001, pp. 210–211) argues that while capitalists may oppose the state in its role of *regulator* (such as in price controls, or taxation), historically they favored the state as a *guarantor* of monopoly. This line of "unthinking" suggests that the market and capitalism are in contradiction, and that capitalism rewards only those able to sustain their capacity to endlessly accumulate capital leaving behind smaller ownership, the labor and, under monopoly, eventually also customers. The "pure" market in the capitalist world-economy is more of an ideology, whereas the state is an integral and necessary element of this economy (Wallerstein, 2004b).

Some of these issues connect with the fifth theme that is the reading of Karl Marx. Wallerstein (2001, p. 3) argues that as a 19th century thinker, Marx "sought to rise above the limitations of his time." What needs reconsideration is how Marx's ideas were adapted by the historical Marxism (or Marxisms) of modern political parties and movements, predominantly those associated with the Second and Third Internationals (i.e., social democratic, socialist and communist). Wallerstein (2001, p. 151) suggests that "Marx would have written the *Communist Manifesto* differently in 1948 than in 1848, and *Capital* differently in 1959 than in 1859. We must do the same." He highlights three assumptions of the orthodox Marxism, which need revisiting or unthinking: the centrality of the industrial proletariat as a force in capitalist processes and as a major transformative actor; the priority of developed countries in progress toward a socialist revolution; and the priority of industrial capital over merchant capital in understanding capitalist expansion (Wallerstein, 2001, pp. 152–153). Additionally, he argues that "Marx was unequivocally wrong" on the presumption that "capitalism represented progress over what existed before, and it will ineluctably be followed by the dawning of the classless society" (Wallerstein, 2001, p. 167). Therefore, a new analysis must also take into account other forms of labor, including informal and unwaged, the political and economic dynamics of peripheral zones, and the fact that "industrial vs. merchant" is a false dichotomy when the totality of accumulation is considered. Some of Marx's concepts that inspired WSA are: class struggle, polarization, ideology and alienation (Wallerstein, 1995).

(Unidisciplinary) historical social science

The sixth theme concentrates on WSA itself as a way to move beyond the older "paradigms" and the location of social science disciplines within them, toward a more open and *unidisciplinary* field of knowledge: *historical social science*. Wallerstein (2000a) described historical social science as

a singular task ... based on the epistemological assumption that all useful descriptions of social reality are necessarily simultaneously "historical" (that is, they take into account not only the specificity of the situation but the continual and endless changes in the structures under study as well as in their enviroing structures) and "social scientific" (that is, they search for structural explanations of the *longue durée*, the explanations for which, however, are not and cannot be eternal) (p. 34).

WSA is not a theory per se but an analytical framework, a perspective combining: (a) long-term macro-historical inquiry; (b) conceptual tools developed by and across different social science disciplines; (c) epistemological and moral reflection on how social realities are studied, what the implications are of the existing methodologies, and how human choices can be informed by social research. Inspired by post-WWII non-orthodox Marxist debates, non-traditional historiography of the French *Annales* school, and Latin American dependency theory, since the late 1970s WSA has become a label for diverse scholarship oriented toward understanding *historical social systems* rather isolated societies (nation-states). WSA situates the processes characterized as globalization in a long-term historical perspective, in two ways. Given basic qualities of the capitalist world-economy (i.e., the modern world-system), we can see that the spatial expansion combined with structural subjugation of new zones was in fact all about the "globalization" of the accumulation of capital. That today we can talk about truly global world-system is a result this very process, beginning in European conquests of Americas, Africa and Asia, and intensifying over the past 150 years or so through

capital mobility in search of profitability and control over labor, using “fixes” that are not only spatial but also technological/organizational and product-oriented (Harvey, 2007; Silver, 2003). Drawing on WSA we can also move beyond thinking of globalization as a linear and inevitable process and rather see the tendencies which indicate the world-system’s structural and historical crisis that demands choices and actions. Traditional disciplinary divisions and epistemological premises are a major limitation and a challenge to be overcome, rather than adequate tools to understand the capitalist world.

Historical social science requires that we unthink a number of common assumptions and consider their alternatives (Wallerstein, 2001, pp. 238–255). Firstly, the disciplinary divisions that were shaped in the 19th and 20th centuries via the formation of academic departments, journals, specialized learned societies etc., enforce intellectual and institutional constraints but do not reflect how humans act. Overlapping occurs between, for example, sociology and socio-cultural anthropology, political science and history, psychology, and education and in all other directions. As an academic discipline, education itself is a good example of multi-disciplinary influences. Moreover, a growing number of fields (rather than disciplines) establish themselves as interdisciplinary, cross-disciplinary or transdisciplinary, and more and more journals and conference calls invite contribution from across a wide range of disciplines. Overlooking of disciplinary boundaries is increasingly seen as a necessary step for specialists researching an issue, and cross-disciplinary theoretical inspirations are also frequent. WSA is an attempt to facilitate such an integrative approach.

Secondly, the epistemological split between the social sciences and humanities, which is captured by the *nomothetic* (oriented at generalizations and theoretical formulations of regularities, or rules governing the social world) and *idiographic* (in-depth description of unique sequences of events and patterns) ways of analysis, is also problematic. This can manifest itself as a clash between social scientists “proper” and historians. However

World-systems analysis offers the heuristic value of the *via media* between transhistorical generalizations and particularistic narrations. ... It argues that the optimal method is to pursue analysis within systemic frameworks, long enough in time and large enough in space to contain governing “logics” which “determine” the largest part of sequential reality, while simultaneously recognizing and taking into account that these systemic frameworks have beginnings and ends and are therefore not to be conceived of as “eternal” phenomena. This implies, then, that at every instant we look both for the framework (the “cyclical rhythms” of the system), which we describe conceptually, and for the patterns of internal transformation (the “secular trends” of the system) that will eventually bring about the demise of the system, which we describe sequentially. This implies that the task is singular. There is neither historian nor social scientist, but only a historical social scientist who analyses the general laws of particular systems and the particular sequences through which these systems have gone.

Wallerstein (2001, p. 244).

Overcoming the nomothetic–idiographic distinction, along with a call for crossing, indeed abolishing, disciplinary boundaries, is a move toward *unidisciplinarity*. This is an organizational as much as theoretical and methodological task. WSA assumes the need for “the wholesale reorganization of the social science sector of our universities and our libraries” (Wallerstein, 2001, p. 272) and, in effect, a transformation of curriculum systems and theorizing about curricula.

WSA also raises the question whether dominant forms of social and historical inquiry have been able to understand the current “moment of transition” of the modern world-system and. If, indeed, these forms of human science crystallized “at the moment of fullest unchallenged triumph of the logic of our present historical system,” they may be conceptually incongruent with the historical challenges faced nowadays. Therefore, WSA proposes a historical social science “that contributes to the transformation of the world by illuminating the choices without appealing to the crutch of a belief in the inevitable triumph of good” (Wallerstein, 2001, p. 256).

A field called *utopistics* is meant as an inquiry into the historical choices in the “moment of transition” or the system’s “bifurcation.” It is described as

the attempt to clarify the real historical alternatives that are before us when a historical system enters into its crisis phase, and to assess at the moment of extreme fluctuations the pluses and minuses of alternative strategies. ... We can clarify the network of forces at work, elaborate possible vectors (and therefore loci of possible conscious interference), and thereby illuminate the real historical choices that are before us. This is not a matter of speculation but of serious research.

Wallerstein (2001, p. 270).

Historical social science and school curricula

How does the WSA ambition for the “rejection of the entire framework of mainstream social science” and its reorganization as a singular and holistic historical social science, relate to questions and debates for curriculum thinking and theorizing within formal education settings? Here we will consider WSA’s potential application to curriculum theory and practice in terms of the rigid disciplinary structure of school curricula globally. The WSA project of unidisciplinary, historical social science can be seen in terms of established theorizing about and initiatives for more integrated and democratic approaches to curricular contents and structures.

At the level of formal curriculum subjects, research has identified a degree of convergence between national systems of education across the globe (Meyer et al., 2017). Acknowledging the inevitable differences between common school subjects found in different countries, and so the limits of claimed curriculum convergence (Anderson-Levitt, 2003), some familiar patterns in the organization

and teaching of knowledge in schools remains. [Anderson-Levitt \(2003\)](#) identified this as the “language arts, mathematics, social sciences, natural sciences, esthetic education, and physical education” (p. 6), but the point is that the dominant model of organization persists: age-based and school subject based classes, with prescribed core curricular contents for school subjects.

The separation of knowledge across school subjects is a curricular problem, reflecting the historical construction of the knowledge disciplines and the organizational dynamics of models of mass school education. In response we find well established lines of argument, and accompanying initiatives, within formal education settings at the levels of policy and practice, to better integrate knowledge from across different subjects, or subject disciplines. [Beane's \(1995\)](#) argument for an integrated curriculum, for example, made the case for shifting the starting point for curriculum organization and contents away from separate knowledge disciplines, asserting that “the sources of curriculum ought to be problems, issues, and concerns posed by life itself” (p. 616). A multi-disciplinary or cross-disciplinary approach follows, in which knowledge contents are selected from across “regular” or established subject disciplines and brought to bear on “problems, issues, and concerns” that students are engaged with. There is a clear influence of Paulo Freire's work here in terms of student involvement in problem posing, connected to their lived experience, as a starting point for setting educational activity including curriculum contents ([Darder, 2018](#); [Darder et al., 2015](#); [Freire, 2014](#)).

An integrated curriculum, from this perspective, “is rooted in a view of learning as the continuous integration of new knowledge and experience so as to deepen and broaden our understanding of ourselves and our world ... It concerns the active construction of meanings rather than the passive assimilation of others' meanings” ([Beane, 1995](#), p. 622). [Apple and Beane's \(1999\)](#) work on a democratic curriculum extends this approach, emphasizing students' knowledge construction that includes the inclusion of non-dominant voices and perspectives, and grounding classroom activity and associated curriculum choices in meaningful problems, events, or issues as experienced by students. The democratic impetus similarly promotes critical approaches to knowledge and knowledge claims or truths about the world, acknowledging the selective, non-democratic, nature of official knowledge in curriculum structures. In this sense, an integrated and democratic curriculum seeks, at least in part, to address the curriculum's role in the reproduction of social inequalities through schooling, and formal schooling's failure to achieve what [Dale \(2007\)](#) described as its “redemptive project” of “severing the links between social origins and destinations” (p. 299).

WSA and its unidisciplinary, historical social science knowledge project, clearly connects directly with efforts to promote inter-disciplinarity within schools. WSA's critique of the disciplinary separation of knowledge, and the associated dominance of (European) scientific universalism, presented the latter as “an essential element in the functioning and legitimation of the political, economic and social structures of the system” ([Wallerstein, 2006](#), p. 59). The disciplinary structures work against the efforts of integrated approaches seeking to ground student learning and knowledge in the urgent social concerns and problems confronting students. [Wallerstein \(2006\)](#) argued that the operation of a capitalist world-economy in pursuit of the endless accumulation of capital, “requires a cultural-intellectual scaffolding to make it work smoothly” (p. 54). Three key elements of this “cultural-intellectual scaffolding” were identified as:

a paradoxical combination of universalistic norms and racist-sexist practices; a geoculture dominated by centrist liberalism; and the seldom noticed, but quite crucial, structures of knowledge based on an epistemological division between the so-called two cultures (p. 54).

Unidisciplinary, historical social science would consciously address each of these elements, tied to a utopistic (not utopian) project of learning and structuring of knowledge that contributes to the political project of transforming our existing world-system (see [Beyond school curriculum: the role of antisystemic movements](#) section below).

Global education as historical social science

Operationalizing an unidisciplinary conception of knowledge for application to school curricula is a challenge, just as efforts to institute integrated or interdisciplinary approaches to knowledge across school subjects confront institutional and organizational barriers. [Aguirre Rojas \(2000\)](#) argued that world-systems analysis has the potential to move beyond the “limited projects to defend and promote a ‘multi,’ ‘pluri,’ ‘trans,’ or ‘inter’ disciplinarity within which, however, the core itself is left untouched regarding the division of social knowledge into ‘disciplines.’ This is the foundation that should really be challenged and radically demolished” (p. 751). Can we envision a school curriculum or university programs that shift away from traditional divisions of social knowledge such as society, politics, and economics; past and present; studies of us and others? And even within subject-based curricula, can we imagine history taught as a way to analyze long term processes and world-scale structures not merely for the sake of studying the closed past but to understand the historicity of our present; or geography classes incorporating socio-economic themes in a similar mode, grounded in WSA; or cultural subjects informed partly by such a framework when discussing intercultural circulation of ideas, marginalized status of some and hegemonic of others?

[Wallerstein \(1997\)](#) is quite explicit about the project of unthinking dominant Eurocentric assumptions, and about avoiding the trap of relying on dominant paradigms to make the critique of European universalism, arguing for example that:

The idea that science is over here and socio-political decisions are over there is the core concept that sustains Eurocentrism, since the only universalist propositions that have been acceptable are those which are Eurocentric. Any argument that reinforces this separation of the two cultures thus sustains Eurocentrism (p. 106).

He affirms this point, asserting that “if social science is to make any progress in the 21st century, it must overcome the Eurocentric heritage which has distorted its analyses and its capacity to deal with the problems of the contemporary world” (p. 94). The broad convergence in school subject disciplines alluded to earlier does not preclude a wide range of particular configurations, including various combinations of subjects into, for example, “key learning areas,” which include multiple more traditional “subjects” being brought together to explore thematic learning areas. For example, schools in New South Wales, Australia, include a “key learning area” of “human society and its environment” which includes subjects of Aboriginal studies, Commerce, Geography, and History (<https://education.nsw.gov.au/teaching-and-learning/curriculum/key-learning-areas/hsie>). Another example could be Poland’s recent introduction of the “History and Present” subject that, while manipulated by the current government and motivated by its conservative nationalism (Starnawski et al., 2021), could provide a promising space for exploring history and its impact beyond dominant narratives of the nation-state and beyond a story of the nation’s glorious events. These are just two of countless examples from across the world, our point being that WSA clearly has a lot to offer to such initiatives, inspired by a historical social science approach.

Curricular reforms like these include “cross curricular themes” that all teachers and subjects are expected or required to attend to, such as attention to Sustainable Development via SDG 4.7 (United Nations, 2015). These reforms are being elaborated within existing systems, linking content selections to central questions of concern to students, societies, and indeed the world. Drake and Reid (2020), for example, note how current attention to 21st century skills development and Problem Based Learning (PBL) supports “an interdisciplinary approach because its underlying philosophy is student-centered, inquiry based, and oriented to big picture concepts and skills applied to real world issues” (p. 6).

One current and promising development in this sort of direction, with ambitions for dissemination on a global scale, is the *Global History of Humanity* initiative, sponsored by the European Union and the SDGs. The initiative involves the production and dissemination of a three-volume *global history of humanity* from 70,000 BCE (Before the Common Era) to the present (Bernardi and Vanhaute, 2021a,b,c). The project is being tested in twelve European countries, with an explicit link to the international SDG agenda, as expressed by the authors:

This textbook is intended as one of the instruments of a broader programme aimed at combining the methods and principles of Global Citizenship Education with the contents of the UN Sustainable Development Goals (SDGs) in school curricula. This textbook and the Get up and goals! project focus especially on quality education for all (target 4.7) and on gender and international inequalities, climate change and global migration. The resulting contents and educational approach aim at overcoming ethnocentrism and enhance students’ ability to place specific issues in a broader and more global dimension.

Bernardi and Vanhaute (2021a, p. 6).

The *Global History of Humanity* initiative offers a current example of curriculum materials, with global ambitions, designed in line with the principles of an unidisciplinary historical social science approach, and with an explicit goal of students “learning from the past to change the present” (Bernardi and Vanhaute, 2021a, p. 16). As expressed by the authors, the goal is for students to “to analyze, criticize, compare, test and broaden our views on the history of humans and the planet they inhabit. This knowledge is also fundamental for making the planet a sustainable, equal, and safe place for all humans, nature and creatures living on it.” (p. 16).

The textbooks take a broad chronological approach, seeking to cover the last 70,000 years through a “firm non-Eurocentric perspective,” and one involving “different time and space scales” (Bernardi and Vanhaute, 2021a, p. 11). The three chronological chapters in each of the volumes are organized not as a linear sequence of events, though simple timelines are included for “readers to remember some significant transformations the planet and humanity underwent, such as climate change and global processes ... [and to highlight] major political and social formations that had global ambitions, like empires and colonial powers.” (Bernardi and Vanhaute, 2021a, pp. 12–13). Rather, each chapter develops a narrative organized into four themes to “look at the different transformations that have occurred in the world” (p. 12). The four themes are: (1) humans change nature, (2) humans on the move, (3) social organization and inequality, and (4) worldviews.

Work like this explicitly and organizationally applies a deeply integrated, historical social science approach to the study of human and non-human history together. In volume 2 for example, Bernardi and Vanhaute (2021b) provide an example of the trajectory of the capitalist world economy in keeping with WSA’s concept of TimeSpace as they describe how “By the 16th century, Western Europe had created new economic and political formations. A radically different relationship between humans and nature was forged; this relationship still exists today and is the root of both the world’s opulence and the present-day problems” (p. 87). Capitalism is defined as a historical social system with

a mode of production that is geared toward “endless” commodification, surplus accumulation and self-expansion. It is very pliable since it has changed the way it functions over time; and it has used different ways of extracting surpluses from nature and labor in different places simultaneously. It is a globalising mode of production that creates inequalities to reproduce itself: spatial inequalities, like the one between core regions and peripheries; social inequalities, including sexual, racial, and inequality between classes. Capitalism reproduces itself to create value from formerly uncommodified nature and human lives. Frontiers of extraction of nature, land and labor are continuously remade and moved to nourish this expansive and unequal mode of production.

Bernardi and Vanhaute (2021b, p. 87).

As with educational approaches inspired by critical pedagogy and working through antisystemic movements, WSA brings a critical angle to education for sustainable development, known also as global education. As pointed by Connell (2020), dominant patterns of critical knowledge on global inequalities or cultural patterns have been typically produced in the “Global North.” Similarly, Buchowski (2004) discussed the “hierarchies of knowledge” in West-dominated anthropology focused on post-socialist Central and Eastern Europe. While such arguments have limitations in that they may divert attention from *what* (an issue) to the potentially moralizing question of *who* (an author and his or her geographic location), they have merit in signaling the problem of the adequacy of concepts and analytical perspectives. Discussing the case of Poland as a former “Second World” and contemporary semi-peripheral country, Starnawski (2015) and Kuleta-Hulboj (2020) attempt to unpack the well-established notions of “North” and “South.” WSA serves as an essential tool in this task as it helps to account for historical dependencies of the given country as a peripheral zone of Europe and the capitalist world-economy, and its contemporary modernization aspirations and contradictions as a semi-peripheral zone within the European Union. The case of Poland is shaped by West-inspired cosmopolitan patterns of imitative modernization on the one hand and nationalist politics on the other, being both a sending and receiving country in terms of migration, advocating environmental policies and continuing to rely on extractivism (coal mining), belonging to the “rich club” of the OECD and having GDP per capita significantly lower than that of capitalist core zones. As such, Poland, along with many other semiperipheries, is not only an example that resists the simple North-South dichotomy prevalent in global education programs, but one that requires a lens that modifies common notions of global interdependencies. The case of CEE countries may also problematize the understanding of peace education, given the existing tensions concerning international security systems, nationalisms, imperialist rivalries and the quest for peace and stability in the post-communist world.

Introducing themes and perspectives inspired by WSA in curricula within national schooling systems requires efforts in educational policy and practice at all levels of scale. In recent decades, initiatives promoting ideas pertaining to global education both within schooling and via non-formal education, have come from educational projects of NGOs and media linked to social movements. WSA’s conceptual framework positions such movements as essentially antisystemic actors striving to change parameters of the capitalist world-economy though until recently mostly limited to concerns of particular social groups (e.g., industrial workers or suppressed nationalities) and mostly bound territorially (i.e., within particular polities’ legislation and electoral systems). Both past and present, and likely in the future, the antisystemic movements should be seen as more than merely partisan or non-partisan actors within nation-states’ political systems and social structures. They also operate as crucial producers of ideas on how to understand and how to overcome contradictions, inequalities, and destructive tendencies of the capitalist world-economy.

Beyond school curriculum: the role of antisystemic movements

Interrelations between antisystemic movements and legitimate knowledge within social and human sciences are central for WSA’s both historical-epistemological reflection and moral concerns. Following Wallerstein (2014) we see antisystemic movements as those emancipatory social movements that: (1) emerged in the “long 19th century” (Hobsbawm, 1973) and unfolded into what was later called the “old Left,” as a response to socio-economic contradictions of capitalist expansion (labor movements and political parties attached to them, most notably social-democratic, socialist and communist ones, and some radical peasant parties too) and a response to imperial, nationalist and elitist political suppression of certain peoples and ethnicities (national liberation, autonomist and abolitionist movements) and women (suffrage movements); (2) challenged the old Left and the post-1945 world order (US hegemony and Soviet alternative) in the form of anti-militarism, the rekindling of anti-colonial, anti-racist and other ethnic struggles, extending activism into areas of gender (second-wave feminism) and sexuality (LGBT+ movements), maintaining universal human rights as a key concept in opposing dictatorships and calling for a turn to environmentalism; and (3) challenged the capitalist world-economy’s transformations in the late 20th and early 21st centuries, commonly referred to as “globalization” (Wallerstein, 2000b, 2005), claimed global solidarity and justice, and sought to reintegrate the “old Left’s” agenda (labor, public services) with some of the New Left’s concerns (identity, certain degree of anti-statism etc.) (Graeber, 2002; Klein, 2000, 2002; Sen and Waterman, 2009; Wallerstein, 2002), yet beyond the latter’s neoliberal diversions (Fraser, 2009).

Antisystemic movements have contributed to the crystallization of dominant modes of knowledge since the late 19th century. Pro-capitalist liberals and conservatives shared a focus on the idea (though not particular politics) of “development” within the nation-state, shared also with radicals, that is, national-liberation movements and workers’ movements. The centrist *geoculture* linked the three ideological strands together, emphasizing—to varying degrees—the triad of civil and political rights, social policies, and nationhood (most notably shaped via the education system and the army, and later via mass culture, e.g., sports). At the same time, the liberal centrism was an ideological foundation for thematic, epistemological, and disciplinary distinctions in the social and human sciences. Since the emergence of the Cold War order after World War-II and the break-up of the colonial empires, research in area studies was pursued with growing cross-disciplinarity. Critical ideas, such as Latin American dependency theory or the perspective of “development of underdevelopment,” produced by the movements and scholars challenging the imperialist and neocolonial dominations, further prompted the shift in focus of social research.

The challenge against the “old Left” was most fully expressed by a series of political and cultural revolts that took place worldwide around the year 1968. These revolts, however distant geographically and specific politically (from Paris to Chicago to Prague and Warsaw to Mexico, Tunisia and Japan) targeted the inability of the old Left to effect systemic solutions to capitalism, which would be egalitarian and democratic at the same time. They certainly targeted the US international hegemony as well but they also criticized the Soviet-style socialism (Wallerstein, 1989, 2004b). And they inspired new paths of scholarly inquiry in social

and human sciences, leading eventually to the establishment of a number of new fields such as ethnic and race studies, women's and feminist studies, sexuality and queer studies, human rights and peace studies, environmentalism etc. WSA developed as an interplay of a search for a critical universalist perspective in studying historical capitalism (and other world-systems) with an understanding of particularity of knowledge(s) as emphasized by the abovementioned new "studies." The shifts in the patterns of knowledge were eventually institutionalized in new departments, journals and learned societies (or new sections of the latter). These transformations should be seen as effected by groups of intellectuals rooted in and inspired by new antisystemic movements, that continue to be essential actors in seeking, formulating, and spreading new modes of knowledge and posing new problems as political and ethical tasks for the generations facing current uncertainties of the future course of the world-system. The movements thus acted more and more purposefully as educational agents.

Various critical pedagogy or critical education traditions have focused on its potential or promise to contribute to action that transforms the world (e.g., [Cho, 2013](#); [Darder et al., 2015](#); [Freire, 2014](#)). Critical pedagogy looks to critical educators within formal education settings to facilitate this sort of action. [Schultz et al. \(2010\)](#), for example, examine the Social Action Curriculum Project (SACP) initiative in a college classroom, involving student-driven "problem-posing" for "real world problem solving" (p. 370). That project, as one of many others, was grounded in a "justice-oriented" conception of education for democracy, and in curricular reforms that were emergent, relevant, and connected to students' "real-life" problems, while still meeting the formal "standards for every subject area" (p. 378). More broadly, critical pedagogy looks to educational work within and by social and popular movements, that connects to such projects for transformative and creative change. [Stetsenko \(2015\)](#) for example argues for a "Transformative Activist Stance" in social research in which the pursuit of the truth about the world simultaneously "creates the world rather than mirrors it" (p. 113); and in which the act of knowing is about "creating the world and getting to know its truth in the very act of bringing about transformative and creative change" (p. 115). Research included in [Darder et al.'s \(2015\)](#) volume includes international examples of social movements as educational sites, such as [Hickling-Hudson's \(2016\)](#) work on Freirean seminar groups in Grenada and theater arts pedagogy in Jamaica, highlighting for example participants increased "ability to challenge and change entrenched public injustices" (p. 259).

[Freire's \(2014\) *Pedagogy of the Oppressed*](#), first published in 1970, continues to be a foundation for critical educators' work across formal and informal educational settings, and within popular/social movements (for a comprehensive account of the scope and depth of Freire's work see [Darder, 2015, 2018](#)). [Freire \(2014\)](#) makes a crucial contribution to work in popular or social movements through his clear and consistent focus on human liberation, on women and men's "ontological and historical vocation of becoming more fully human" (p. 66), and so the pedagogy of the oppressed as "the pedagogy of people engaged in the fight for their own liberation" (p. 53). The text is grounded in the capacity for cultural and educational work that facilitates liberation as praxis—critical reflection on the world that becomes action to transform the world, avoiding both "verbalism" that stops short of action, and misguided "activism" without serious critical reflection. [Freire's \(2014\)](#) explicit purpose is to work toward people's "adherence to liberation" (p. 168), not through the imposition of an alternative worldview, but through dialogical teaching that involves the "the organized, systematized, and developed 're-presentation' to individuals of the things about which they want to know more" (p. 93), effectively re-presenting reality as problems. The liberatory purposes of Freire's approach, fixed firmly on critical reflection and action to transform reality, connect clearly with WSA's focus on systemic transformation. To cite just one example, [Wallerstein \(1998\)](#) highlighted the need for intellectual work that involved both the critical understanding of social reality and the creative imagining of utopistic alternatives expressed as an "alternative, credibly better, and historically possible (but far from certain) future" (p. 2), followed by political action guided by the project of constructing such alternatives.

[Wallerstein \(2014\)](#) pointed to a paradox about the antisystemic movements. While they challenge the institutions of the capitalist world-economy, at the same time such movements are themselves a product of it, which means that hitherto for the most part massive efforts lead to changes *within* but not *of* the world-system. Wallerstein argues that at the point of bifurcation shaped by the structural crisis of capitalism and its ideologies, and characterized by growing uncertainty about the future of the planet and humanity, there may be more hope for various political efforts to have a lasting, that is, transformative impact on the world-systemic level. The ultimate direction and the results of such efforts cannot be predicted, and the capitalist world-economy may transform into a more exploitative and more authoritarian world-system. Still, the bulk of contemporary antisystemic movements work on ideas and actions aimed at achieving a world-system that would be relatively more egalitarian and more democratic than the world we know. While mainstream social sciences study social movements and political behavior, Wallerstein's notion of *utopistics* meant a more far-reaching task for politically and morally informed scholarship, that is, a systematic reflection on historical choices that individuals and populations are facing in our times.

We focus on the notion of critical studies as concerned with power as a productive force governing exclusions and abjections in its drives for inclusion. Our direct attention is to the infrastructures of pedagogy and research as the affective and cognitive structuring of body and soul. The infrastructures configure and distribute categorical differences about kinds of people through a comparative reason that creates spaces of action. The political lies in the distributions of differences. The effects of power are elided in representational logics of the critical studies in education; at least in the structural and phenomenological traditions populated in Anglo-American traditions. Our strategy is to make visible and thus disrupt the productive rules and standards of the procedures of othering. The representational logics in social and education research

are practices or operating mechanisms which do not explain power, since they presuppose its relations and are content to “fix” them, as part of a function that is not productive but reproductive. There is no State, only state control, and the same holds for all other cases.

(Deleuze, 1986/1988, p. 75.)

The arguments enter into a non-representational logic that eschews the philosophical distinctions of nominalism and realism that have driven critical studies in education. A non-representational approach takes the onto-epistemic forms of the representations of people as having a materiality. The materiality occurs as the representations of people and events “act” as transcendental objectifications of the “Real” and “World”, calculative spaces of action that exclude and abject in the borders of its inclusionary thrusts (Popkewitz, 2020).

The chapter is organized in the following manner. The first section considers the connections of the affective and cognitive structuring of schooling as a material “actor” in the governing of modernity. Our main concern is the comparative reason that fabricates kinds of people through distributing and governing *differences*. This logic and principles, we argue, are elided in the structural and phenomenological traditions of critical studies populated in Anglo-American contexts. The next three sections focus on the affective and cognitive infrastructure in the reason of schooling to examine how the exteriority of representations—abstractions of people, time, and space—constitute architectures and topographies of the subject, the body, and the soul. The affect inscribed in the infrastructure of knowledge and critique embodies desires and potentialities that act as aspirations and fears of the dangers of difference and particular populations.¹ The infrastructure, we argue, invents and stabilizes the comparative reasoning of difference as agential spaces of actions that cross reformist and Hegelian logics in critical theories of education.

The chapter draws on a spectrum of studies related to post-colonial/decolonial and feminist studies and the new materialism as they relate to the field of curriculum studied in education. We engage the broad band of studies but not to find a homogeneity. Our task is to intellectually “play” with the nuances, distinctions and dispositions of these studies to explore the political of knowledge at the interstices of the modern education.² It directs attention to “what is accepted as authority through a critique of the conditions of what is known, what must be done, what may be hoped” (Foucault, 1984, p. 38). Critical theory, as argued here, brings into view an agential notion integral to the Enlightenment attitude toward reason as *critique*.³ The critique we engage is to resist the political of educational practices; their spaces of normalization, differentiation and abjection in their concreteness that are never merely of schooling.

¹For general discussions of affect, see e.g., Deleuze, 1986/1988; Anderson, 2010, 2014; Brinkema, 2014; in education, Demikos et al., 2020; Lesko and Van den Berg, 2019.

²Our use of *modern* and *modernity* are not to suggest a particular epoch or period, but as to think of the particular interstices of historical lines that change over time in epistemes that “act” affectively and cognitively as fold and folding to calculate and produce comparatively kinds of people (see, e.g., Popkewitz, 2008).

³For this discussion, see, e.g., Blumenberg, 1966/1983; Foucault, 1984; also Popkewitz, 2008, 2020.

The political: fabrications in the making of kinds of people

The notion of critique that we engage considers the affective and cognitive structuring of schooling as a material “actor” in the governing of modernity. The art of governing is examined as an infrastructure, the historical and material (re)configuring of differences as a comparative reason fabricating kinds of people.⁴ At the interstices of the Enlightenment, the welfare state, and coloniality that emerged in the long 19th century and continue today are different settlements in governing the distributions of differences. The governing practices perform as the political through its representation logics and onto-epistemic principles. This logic and principles, we argue, are elided in the critical studies populated in Anglo-American traditions.

The art of governing: reason and fabricating kinds of people

The formation of modern nations recognizes the importance of governing through the production of particular kinds of people whose participation was necessary for government. The politics of the state entails new relations and practices. Collective belonging joins with notions of the family, civil participation and the self-governing of individuality as a productive apparatus of power that is different from the prior practices of a sovereign, the Church or the Emperor.

The notion of the welfare state expresses the new relations. The state entailed a reciprocity that operated in care of people to connect public projects with subjectification, acts of inscription of moral order in the economy of the family and schooling that include the invention of childhood that traverse the late 19th up to today (see, e.g., [Hultqvist and Dahlberg, 2001](#); [Zsuzsa, 2014](#)). The spatiality and sociality were intimately, although indirectly, bound to modes of living, and interiority as the degrees of individual freedom.

This governing was not merely the art of governing of the modern welfare state but the economy of subjectification and coloniality. It entails the emergence of an apparatus that connects cognitive and affective structures to calculate representations of people and events. The objectifications of people entail identifiable forms that generated the possibilities for codification and administration. The creative child, for example, is a particular way of thinking, differentiating, and ordering who the child is and should be; a comparative way of thinking about the child who is not “creative” that appears in the 19th century as a concept of science (See, e.g., [Martins, 2017, 2018](#)). The representations of kinds of people, however, have certain specificities that are not merely reproductive and isomorphic, sharply delineated lines but entangled in multiple and mobile lines that are rearranged and reinscribed in settlements of different cultural and social spaces.

Science was a practice that embodied a calculative knowledge. That knowledge was given as the apotheosis of reason as wisdom itself by the turn of the 20th century. Science was the sacred knowledge that connected and generated desires about the potentialities with theories and programs about human development. While with debates and dissents, the European Enlightenments sensibilities about human reason and science were brought into the formation of the republics as salvific themes about collective belonging and the redemptive themes that gave optimism to the potentialities of the future ([Becker, 1932](#); [Bercovitch, 1978](#)). The optimism and potentialities, we will argue, were double gestures in which the anterior topography of the differences were inscribed in the interiority of the body and soul.

The economy of subjectification and coloniality was embodied internationally in the New Educational Fellowship and American Progressive Education in the early decades of the 20th century. An idealized and analytic notion of scientific method as a mode of thinking and logic of classifying the objects of the real world was assembled in the pedagogical practices and the modern school curriculum. Embodied in the notion of scientific method was a logic that instantiated cultural theses about the responsibilities, modes of living, and dispositions of kinds of people ([Rudolph, 2019](#); [Kirchgasler, 2017](#)). The notion of the adolescence, for example, embodies cultural and philosophical ideals of the “adult” that the adolescent is not, yet to become and, at the same time, thinking of “youth” as a period of “natural” transition where the deviances and moral disorder of urban life can be controlled.⁵

The science of observing and governing bodily as preemptive logics of psychology operated as the affective economy. The social sciences, psychology and anthropology folded into pedagogy as an affective and cognitive structuring of indigeneity. Guatemalan schools at the turn of the 20th century produced sciences and a visual culture that differentiated “the Indian” as the exotic other whose body and soul were objects of abjection and civilizing ([López, 2013](#); [Lopez and Coello, 2020](#); also see [McLeod and Paisley, 2016](#)). The normalizing and differentiating capacities of people inform today’s education through ordering how to observe, classify and govern the hyperactivity, attention-deficiency, as well as boredom, depression and lack of motivation among American youths. The care and governing of bodily capacities are often built upon a racialized perspective, for example, of a young, American black teenager as “moody” ([Lesko, 2001](#)).

The reason of sciences is not merely the structuring of knowledge. It has a materiality as the infrastructures in pedagogy are attached to the body and soul. The continual objects of change are the interiority or “the soul” and the body. Modern governing no longer addresses the body and soul as binary categories, instead, the body is turned into a non-corporeal reality and the soul is made into domains of knowledge in the infrastructures of pedagogy and psychology ([Foucault, 1978](#)). [G. Stanley Hall \(1904/1928\)](#), one of the founders of the child study movement at the turn of the 20th century, argued that the psychology of adolescence was to work on “the soul” of the child. Psychology was concerned with the inner moral qualities and characteristics of people that

⁴Our use of infrastructure has homologies to [Kuhn’s, \(1970\)](#) notion of paradigm and [Hacking’s, \(2004\)](#) styles of reasoning. Linking infrastructure with reason in this chapter is to give greater attention to the materiality of epistemology and ontology as a historical practice related to the body and soul.

⁵This relation of giving a nature to things and moral order in science is explored in [Daston \(2019\)](#).

are today expressed as changing people’s “behaviors”, “dispositions” and “mindsets,” that later as not merely about ideations of the mind but as modes of living and being. The non-corporeal “soul”, argues Foucault, is given historically as the power/truth in mastering the body as the bodiless reality. The soul inhabits the body and brings the subject of the child to existence, and “the soul is the prison of the body” (Foucault, 1978).

Fabricating kinds of people: the exteriorities of interiorities

We focus on the practices of pedagogy and its sciences as folds and folding structuring people and differences through its onto-epistemic representations. We initially approach schooling as the fabrication of human kinds. Fabrication is to engage two seemingly different and oppositional meanings in talking about education; that is, the determinant categories that represent the subjects and objects of schooling are simultaneously fictions and a materiality manufacturing differences of kinds of people.

But fabrication is more. It provides a way to explore how the exteriorities of the forms of knowledge work to produce the interiority of the body and the soul. The psychologies of the child as a learner, youth and the adolescent, for example, are desires about the kinds of people that schools are to produce. The notion of the youth and the adolescent child were fictions at the turn of the 20th century, for example, to think about, classify, and plan for correcting the moral disorders associated with the new urban populations that were coming into mass schooling of Western Europe and North America.

The fictions become spaces of action in the manufacturing of kinds of people. The classifications become determinant categories about people that are taken as real. The classification of teachers, social worker, family and community become categories whose objectifications act on as modes of living for the adolescents’ transition to adulthood and make possible the potentialities, for example, of the creative, or the scientifically able child. The classifications connect individualities and communities as a particular intimate closure in a field of futurity. The adolescents’ experience, memory and passages of becoming are enclosed and interned in the anticipated potentialities. They function in everyday life through theories, programs, and stories. The classifications are no longer only to think about people; rather, the categories work their ways into what teachers, children, and family do and the degrees of freedom associated with the actions.

What appears as single objects for reflection are formed through multiplicities; a complex assemblage of ideas, concepts, technologies and principles that produce the objects as “actionable”. These multiplicities of historical lines and foldings of affect and the cognitive structuring are given as settlements of human potentialities and *subjectification*. Notions of childhood and youth, for example, entail folds of political theories of government, abstractions of *the* people, probability theories of populations, and psychological ideas of childhood in the long 19th century to manufacture the citizen as new kinds of person.⁶ The cognitive structuring embody folds of feelings and emotions inscribing particular cultural and normative settlements in the distinctions and ordering practices about the child and childhood in school programs (see, e.g., Friedrich and Colmenares, 2017; Zhao, 2018).

The fictions work into everyday life and have a materiality for ordering of experiences and the degrees of freedom about who people are and should be. The fabrications are spaces of action. The psychology works into the schools as a place where children go in the making and revisioning of the interiority of people. Pedagogy, curriculum and the sciences of learning are the sacred knowledge to effect that governing. The concerns with learning science, mathematics and civic education, for example, occur at the spaces of social psychologies and of the child that work affectively and cognitively as anticipatory to order and “develop” the modes of living of the kinds of people that children are and should be. These kinds of people are often named today as the child who will be an active, participatory, lifelong learner and the mathematically able child. But the names are more than names as they have a materiality in the designing of practices that anticipate modes of living.

The fabrications work as an exterior to enunciate pedagogical designs of an imagined interiority of the able, satisfied, self-motivated and engaged child (Yolcu and Popkewitz, 2018; Andrade-Molina and Valero, 2015). Assembled as an alchemy, the spaces of production in science, mathematics, and the arts are reterritorized in the knowledge practices of schooling as analytics of the subject content of teaching. (Popkewitz, 2018). Phantasmagrams of modes of life are produced through the temporal and ontological distinctions that order the objects of effective teaching, efficient children’s learning, and imagined families and communities. The curriculum is a fold with psychologies about the potentialities of who the child is to become (theories of learning). The body and the soul becomes objects of pedagogical observations activated as learning, attitudes, motivation, and “civic” virtues.

The issues at hand are not the particular naming of the child as representational objects, but how the determinant categories are assembled and connected in particular historical grids that govern the possibilities of existence—making of kinds of people. These possibilities are performed on the body and the interiority or the soul. Today that soul is spoken of as changing teachers’ habits of mind sedimented into the organizational language of benchmarks and empirical evidence. These fictions embody “the double gestures” that we explore later. They affectively generate the hope of progress and fears of populations that prevent that progress (Lesko and Talburt, 2011; Ó, 2003, 2005; McLeod and Paisley, 2016; Kirchgasser, 2019, 2020).

The double quality of fabrication as fiction and manufacturing is given reference to what Hacking (2004) has called dynamic nominalism and Barad (2007) agential realism. The notions of fabrication as a fiction and manufacturing of people correlates

⁶While there is a particular philosophical literature that links the contemporary political idea of the citizen to the Ancient Greek cities, that evolutionary and conceptual history homogenizes and loses site of the historical distinctions of time, space and cosmologies through which life was ordered and its modes of life (see discussion of this issue in Popkewitz, 2008).

to a range of non-representational theories that cross feminist theories that make gender and sexuality as a cultural practice that intersects with the body (Butler, 1993; Judovity, 2001), theories of racialization (Bullock, 2018, 2019; Koza, 2021; Lopez, 2017; Hall, 1986; Gilroy, 1993; Weheliye, 2008; Dixon-Román, 2016; Wynter, 1996, 2001; Pinar, 2004; Britzman, 1991), and post-colonial and de-colonial studies (Spivak, 1999; hooks, 2014; Wynter, 2003; Paraskeva, 2016; Lopez et al., 2019). The corpus of work entails questioning the onto-epistemic principles what is known and how that knowing occurs.

The politics and the political of schooling

The different historical enunciations in the making of the subject are elided in representational logic of the critical studies in education; at least in the Anglo-American traditions. These studies follow undulating pathways given visibility in the middle of the 20th.⁷ That literature, represented in different ways, in the early 1970s educational sociology about “the hidden curriculum.” Expressed in Philip Jackson’s *Life in the Classroom* (1968) and Michael F. D. Young’s *Knowledge and Control* (1971) the concern was with the reproduction of social class structures that exclude. The focus on social class explored, for example, how accountability and reform programs harmed particular social and racial groups produced, inequality, and denied minority community right, voice and representation. Today class has either disappeared or intersects with the objectifications representing race, gender and ethnicity as determinant categories to account for how dominant group are represented in the school to reproduce inequality. Populated with concepts like ideology and hegemony in educational anthropology and sociology of education as well as curriculum studies, differences are expressed today within a universalized, globalized framework of neoliberalism viewed as embodying practices of domination and reproduction.

The politics of representation in these critical studies have been important to political movements to challenge the effects of inequality produced and reproduced in modern institutions. The exclusion produced in welfare and educational institutions through denying or limiting access and opportunities have provided new avenues for the struggles of equal rights. The phantasma of the harmonious world occupied by Northern European and North American families living in white picket fence houses in childrens books are no longer adequate as providing the futurity of education. Questions of diversity, differences and multiculturalism have become mainstreamed in the study of the practices of schooling.

Referenced primarily with Frankfurt critical theory and Gramscian notion of hegemony, Anglo-American critical research has particular limits and paradoxes in enacting its social commitments. There is a duality of the utopic that co-exists with a realism of zero-sum world. The realism embodies and defines representations of different social groups as transcendental signifiers to explain the origins of inequities and correcting the social wrongs. The categories carry the utopic dream of a world that, at least, theoretically, the subaltern or indigenous speaks through the right guidance of Reason as the originary forces of power.

The aporia of the realism manifests in where difference is made thinkable, malleable and subjected to styles of critique. Diversity, a concept valorized in biology, is difference measured, universalized to a presumed, utopic vision of progress and future. The comparative reasoning in the theory of difference manifests what Wells (1938) refers to as a strict parallelism in which categorical and conceptual differences—habits, cultures, races, genders, traditions, etc.—are welcomed but ultimately should be mediated and directed by sameness. The critical pulses are homologous to the grand inclusion in the long nineteenth century when the social problems—the workers, sinners, criminals, the poor, etc., were invented as determinant categories of deviance displaced outside of the individual or religious enterprises of philanthropy and included and incorporated by the state apparatus. The new images of the marginality are objects of knowledge, hospitality and desires of critique institutionalized into the system of self-other relations anticipating a utopic futurity—a symptom of a cruel optimism of the hope of the good life that produces its Others as outside of its liveable spaces (see, e.g., Berlant, 2011).

The zero-sum world represented in the critical research is that of the absolutes of the sovereign and disciplinary power. The world is divided into binary categories of populations that differentiate those who dominate and rule from those who are ruled and repressed. The production of differences embodied in the representations function as the originary points of the real and change. The realism of the objectifications work as a sum-zero game world to define freedom in absolute languages of empowerment, voice, and inclusion, among others. The acts of freedom and empowerment are historically given as outside of the relational assemblies and connections in which they are produced.

The major differences between earlier research and its more recent elaborations of critical theories of education are the changes in subject matter, sometimes with the languages that have resemblances of the non-representational theories but maintain their representational infrastructure (see, e.g., Braidotti, 2013). The conceptual and categorical differences are inscribed in a representational infrastructure that operates with the question of “how” to re-configure and redistribute the relations of the other who becomes natural but not completely true yet (Anderson, 2016). The promotion and articulation of “diversity”, for example, manifests to subjugate *difference* to the coordinates of the unified normativity of the subject, problematizing and “correcting” the disdainful misrepresentation and stereotyping of the minoritized.

The colonial story of the traveling critical theory rarely explores the principles of representation and the realism of the subject as the system of reason that overtly forms its problem. The narratives are of a global history of governing the social and psychic life of

⁷We are casting a general statement about particular principles that seem to cross a wide range of educational literature. We can also differentiate the Anglo-American literature in education to that of Latin American and Japanese Marxist traditions; different from critical literatures of Latin American Liberation and the Catholic Worker Movements, the latter in the work of Pablo Friere but which was given its neomarxist theoretical grounding as it traveled by his interlocutions in North America.

the colonized, of seizing the body and soul of the indigenous and incorporating the reproducibility of a historically particular fold in Western conscience, knowledge and emancipation. The procedures of truth and sublimation traveled with the medical missions and ethnographic science alongside the imperial expansions to Asia, Africa and Latin America in the early twentieth century, and further institutionalized and dispersed into various pedagogical languages and infrastructure to perpetuate the self-other relations. A “non-polemic” space is produced where the apparition of the sensible builds up a hierarchical humanism that traverses the subject to render the marginal in the inscriptions of their own condition (Rancière, 2004).

The style of critique in the studies of the politics of representation misrecognizes the politics of schooling for the political. Politics, the political theorist [Jacque Rancière \(2006\)](#) argues, is the policing of the boundaries and hierarchies of the sensible (and the sensibilities of that sensible) as the object of change. The epistemic structuring and ontologies that maintain the contemporaneous frameworks are re-language but not undone with the politics of representation. Left unscrutinized is a critical analysis of the onto-epistemic principles through which the objects of reflection and action are produced. The normative positiveness of change inscribed in research ignites the sense of the possibility for transformation that creates its own impossibilities. The affective desires for change by centering on “the Child” is assembled as a particular futurity that abjects queer bodies from the boundaries of spaces of the inscribed normalcy ([Edelman, 2004](#)).

Our attention is to a notion of critique in this chapter resonances with Rancière’s differentiating of politics from the political. *The later is the historically enunciated partitions of the sensible and, we can add, the sensibilities* that encloses and interns the partitions of the sensible as the real and materialities for action. [Rancière’s \(2006\)](#) notion of the political has a homology to Deleuze’s theory of difference and repetition, [Foucault’s \(1979\)](#) notion of governmentality and knowledge/critique as cutting concerned with the principles generated in governing the production of desire and potentialities.

Affect: attachments of desires and potentialities

The infrastructure, we have argued, entails affective and cognitive apparatus as folds and folding in the making of kinds of people. This focus is a “decentering” of the subject that Foucault spoke about to examine the inside of the exterior that constitute the representational objects as the phenomena of schooling. [Deleuze’s \(1986\)](#) reading of Foucault viewed this radical critique to “continually submits interiority” (p.53) to the outside that is not fixed. The folds are animated by uneven movements of historical lines “that together make up an inside: they are not something other than the outside, but precisely the inside of the outside.” (p. 54) This strategy brings the interiority (of thought, as the unthought; as finitude, as the ground of subjectivity) to the surface, made exterior to constitute a new topography of the subject, the body, and knowledge in the process ([Brinkema, 2014](#), pp. 22–23).

At this point, we explore the exteriority in the mapping the typography of the objects of schooling as embodying an affective structure. The affective is not as a subsidiary quality of knowledge but entangled in what makes legible the expertise of science, for example, as it settles in policy, social debates, pedagogical practices and research. The focus on affect directs attention away from emotion, feeling, tears, awe, sensation, and aesthetics as a function of moral sentiments, psychological categories of the interior states of individual, or as an identity that functions as entry into the knowledge of a subject ([Brinkema, 2014](#)).

The focus on affective attachment to infrastructures of social life indicates how an exteriority of knowledge holds for and directs aspirations and fears that constitute its inside and interiority. The anticipatory promise of the calculations representing of youth as a category of a kind of person, for example, embodies national and personal aspiration and fears of dangers of diverse publics ([Lesko and Niccolini, 2017](#)). Inscribed as the spatial configuration and distributed in the determinant category of youth is the fabrication of a kind of person, produced in the infrastructure that enables and designs an exteriority to govern the interiority by seizing, dispersing and governing attention, perception, energy and “mood” ([Kowalczyk, 2014, 2016](#)).

Affective structuring works as desires of what should be done to shape action and to manage living. Acting in the rationalities about life and people are the inscriptions of desires about the potentialities of social life and humanness anticipated ([Deleuze, 1995; Deleuze and Parnet, 1977, 1987; Agamben, 1999](#)). Folded in the infrastructure, desire is considered a substantial force of life yet it is directed to what is to be changed and what should be. Inscribed in schooling are desires, express as, for example, the potentialities of kinds of people such as creative child, the expert teacher, and the nurturing mother. The desires are not psychological interiority but the becoming of a historical reality, a predisposition that regulates actions through routine anticipations, habitual responses, patterns of recognition as unconscious and non-conscious characteristics.

The production of desires are elided through different historical lines given as the “non-polemic” space that tells of the truth of schooling. Prominent in this elision are the calculative practices that represent the achievements of students through statistical indicators and indexes of national conditions of education. The OECD’s International Student Assessments, for example that compares approximate 100 nations education is taken as providing for the competencies and well-being of nations and societies. The statistical knowledge and numbers seem as having a mechanical objectivity. *The charts and graphs, however, are imbued with representations that move and mobilize* ([Popkewitz, 2020; Popkewitz, 2022a; Anderson, 2010](#)). The numbers and statistics are embedded in a visual culture that is not merely descriptive of educational conditions ([Dussel, 2013](#)). The data and facts are generative of emotions and feelings, inviting and tasteful as an something that is working toward the fulfillment of national aspirations and in processes of subjectification as actualizing students ability to be economically productive and emotionally prepared for the demands of the uncertain future society that they will encounter.

The affective quality of knowledge is a fold in the calculated domains of numbers visualized in tables, charts, and graphic images. The indexes of educational attainments act effectively to engender an optimism that change can prevent catastrophes in which nations fall behind in the mists of the transformation as well as bring about psychological “well-being”. The statistical calculations visualized in the lists and ranking of PISA generates indexes to locate the progress or failure of nations to grasp the utopic world that PISA assessment assumes and anticipate. The titles of reports, for example, express the measures as significant in locating what nations have to do to stay at the top and what nations need to do to sustain growth and development guided through PISA’s expertise.

The desire of potentialities are formed as philosophical ideals embodied in the classifications and distinctions through which probabilities theories of the statistics are applied. In the international assessments, desires are embodied in the distinctions about children’s academic success assembled with notions of literacy, well-being, motivation, and participation. These qualities of the child are connected as the potentialities of the economic and social prosperity through the pathways identified in the OECD models of change. Generated through the infrastructure are conceptions of the modes of living and dispositions about future needs that are not empirical or evidential, in the sense of merely descriptive of what “is”.

The affective interface between collective belonging and the body and soul is embodied in the cascades of data. The knowledge and skills measured are spoken of as representations of the *literacies, competences and benchmarks* that children need for global competence of the anticipated future (Popkewitz, 2022a). Literacy is affective, a plurality that is “constantly infusing embodied practices, resonating with discourses, coalescing around images, becoming part of institutions, animating a comparative reason in catalyzing political communities, and being known and intervened in, among much else (Anderson, 2014, p.6)”. “Literacy”, at least European contexts, reserved for learning how to read the bible is transposed affectively to generate the necessity of the successful participation in modern societies. Its affect is of a generic, general world, inhabited with a cosmopolitanism that students possess for competence in navigating a global world not yet here but filled with uncertainty. The assessment’s affect of literacy activates desires of potentialities of the reasonable and rational person preparing for the indeterminacies through determined rational knowledge and skills.

Temporal ordering and the desires of differences

The reasonableness given to kinds of people and events of schooling never occur in solitude, but collectively and historically formed within a temporal ordering. Time becomes a social attribute in the identities of differences and changes of human life that crosses reformist and Hegelian logics. Time becomes a social “fact” ordered as processes that compare human development, evolution, and growth. The regularization, irreversibility of time made possible new forms of memory and forgetting that were tied to external sites as museums as a representation of human qualities and characteristics as marks of difference. The past, present and future are placed into “the arrow of time” that moves within the pedagogical practices as well as revisioned in the Hegelian notion of dialectics (for latter, see, e.g., Brinkema, 2014).

The significance of time is its assemblage as a fold in the comparative differentiating of people in hierarchies and continua of values.⁸ In the nineteenth century, for example, there occurred the rise of a wholesale awareness of change, the future, and history, with a Faustian desire for the knowledge of becoming, rather than being. The Faustian becoming brings the relation of the past and the present as giving direction to the future that science anticipates. Research rearticulates and (re)visions John Stuart Mills’ expression: “the idea of comparing one’s own age with former ages, or with our notion of those which are yet to come, had occurred to philosophers; but it never before was itself the dominant idea of any age” (Eksteins, 1985, p. 3).

The movements of a regular, irreversible time focus human attention and perceptions around processes that stabilize the representations of identities by which differences are defined. Linked with the irreversible movement from past, present to future brings into view principles of change, differences and their administration through calculating everyday experiences, such as found in studies of households and labor. The past inhabits the conceptions and classifications that give intelligibility to the objectifications of the child’s development and growth for example, in configured spaces that generate potentialities. The intersection of past, present and future is captured in the notions of youth and adolescent as transitional stages of life, represented in the social and psychological sciences.

Time is an element of subjectification—that is, how the exteriority of forms and knowledge order the interiority for feeling and giving meaning to experience and the trajectories of one’s life. Cultural changes in the 19th century, for example, made it possible to think of one’s life as governed with a planned trajectory of biography in “the arrow of time.” This planning in the arrow of time was articulated in the idea of people having careers, a word that previously described racetracks for horses (Bledstein, 1976). The idea of a career, however, was not only about an individual planning a life but was intertwined with the emergence of the expertise of professional theories for codifying and standardizing who people were and could be as a course of life.

The recognition of people to be included and as different, paradoxically, establishes continua of value between *normalcy and pathology* that haunt the social sciences and psychologies related to education (Popkewitz, 2008). The assemblages of sociality and individuality in the sciences bound critical pulses with the grand inclusion in the long nineteenth century. New distinctions of kinds of people were given as the origin of the social problems, reclassified in the ideas of the workers, criminals, the poor and racialized groups. New forms of philanthropy, the emergence of welfare institutions and settlement houses, social science, and the modern, common school wove into the art of government.

⁸Carl L. Becker, *The Heavenly City of the Eighteenth-Century Philosophers* (New Haven: Yale University Press, 1932).

Installed in this governing was the notion of social and individual improvement as utopic (Hetherington, 2001). The new sociologies and psychologies associated with American Progressive pedagogies and its sciences,⁹ for example, gave focus to the undoing the moral disorder of urban life and its populations (Popkewitz, 2020). With the introduction of “normal schools” in the middle of the 19th century, the professionalization of the teacher concerned the “awakening” the moral character, later replaced on training in communication skills and the standard techniques of teaching (Lee, 2020).

The cultural space of childhood becomes a temporal ordering in the making of the interiority of the “child,” (see, e.g., Steedman, 1995). Today formed as fictions about modes of living, concepts as adolescence, the lifelong learner, and the disadvantaged child instantiate the spatial unity of the whole from which differences are registered through processes of “learning” and notions of well-being, engagement and “grit”. The processes stabilize the unity as representations from which a comparative reason differentiates and divides the qualities, and capabilities of the child. The distinctions and differentiations embody an unspoken but present normativity about the interiority of the child who lacks motivation and engagement and of the “fragile” (or “chaotic”) family.

The representations of the child are stabilized, transcendental signifiers that locate the origins of change. Time as processes become the object of change. The objectifications are represented as the identities of the populations. Change becomes the processes of remediation, rescue and redemption for entrance to the closed space of society and its “humanity.”¹⁰ The stabilizing of space and the privileging of time produce systems of exclusion and abjection. The desires of potentialities generate double gestures that distribute differences about the kinds of people in the enclosed “other” spaces of a temporal order; the “urban” populations of the turn of the 20th century and the 21st century as urban populations who “lack” self-esteem, engagement, grit, and motivation-people and families abjected as being consigned to unlivable spaces (Popkewitz, 1988/2017; Popkewitz et al., 2017; Kirchgasser, 2016, 2018, 2019).

The representational reasoning in the infrastructures of schooling and its sciences conceptually and physically banished populations as not being of *the average*, a concept of space ordered through time. The objectifications that represent and identify differences in a temporal order cast out kinds of people who are made as strange, “foreign,” racialized, and as endangering the future. The principles of comparison reside in the distinctions and differentiations around who the child is or is supposed to be as the norms that produce the unity, but also around its “others,” who do not fit into these spaces of normalcy - the immigrant, the member of an ethnic and radicalized populations, and the child today who falls into the achievement “gap” and is left behind. The representations revision the structuralism and realism of the rulers and ruled into the binary resignified as the learner and the disadvantaged. The production of comparative reason entails, as Casid (2015) argues, “the colonial machinery of dominance” (p. 122).

Locating the homeless and location-less reason

The different dimensions of affective and cognitive structuring that we have explored are entangled with a particular kind of consciousness of modernity. That consciousness embodies particular kinds of abstractions that “act” as representations or determinate categories about kinds of people and differences in social and personal life.¹¹ The abstractions of society, individuality, and populations are such examples that emerge in the long 19th century. They produce phenomena that no longer have a direct relation to the conditions of human activities but arrive as “homeless” and location-less concepts and calculation of life outside of bodies. The homelessness and location-less logic makes childhood as a particular “space” in which time is developmental, turning the child into a prophetic, governable surface and interface. The child becomes an object of its own history contained within notions of nature that brings to bear its contextualization as the movement of stages of development and transitions. The child is objectified through coordinates promoted through affects of potentiality of the good life and flows of experience and memory into universal, flatten spatial relations in a regularized time. The relations of childhood seem to have no history or social location to authorize it other than coordinates of its interior conceptualizations.

The abstractions are universal, globalized concepts without any home or historical location, what Deleuze and Guattari (1980/1987) express as the deterritorializing and reterritorizing. The abstractions of childhood and the citizen, for example, remove the immediacy of experiences by deterritorializing their coordinate in space and time and reterritorialize experiences as phenomena that can be calculable and as seemingly objective knowledge actionable in many different spaces. Whether in China, Spain, Ethiopia or the United States, the abstractions of child appear as universal and real distinctions in teacher education, psychologies and the school curriculum. Generated as seemingly global principles about the potentialities of the child, the abstractions “act” as determinant categories of people that hold promises, although in different ways, of collective progress, individual participation, and the competence for future success. The images, interfaces, and concepts created appear as transcendental planes about life, learning and the self that seem to have no cultural and social boundaries.

The distancing practices of these abstractions enable reflective practices that narrate a human history, collective belonging, and the self in a flow of events that have little to do with face-to-face relations. But the “explanations” create coordinates of those relations that have a materiality. To return to the earlier notion of literacy, it is an abstraction of a school subject historically formed in

⁹The use of Progressive not to delineate a sharply defined temporality given to the past; its configurations embody multiple folds and folding of historical lines that produce objects of desire and change produced, hence the phrase “the long 19th century.”

¹⁰For counter-narratives, (see, for example: Ariès, 1961/1962; Dekker, 2010; Finkelstein, 1989).

¹¹We are focusing on a particular quality of homelessness as it relates to universalizing kinds of people as determinate categories from which differences are produced. As a broader historical mode of reasoning, this quality of distancing, abstracting and ordering relations is embodied in this argument but with different historical and relational approach.

the designing of the religious soul of the child through pedagogical practices that in the late 19th century was a normalizing practice related to national belonging that simultaneously differentiated the abled body from those disabled and abjected (Green, 2003, 2017; Cormack and Green, 2009; Hunter, 1988).

We can now explore more specifically the materiality of the epistemic-ontological principles of schooling. The homeless, location-less phenomena produce relevancies in which dimensions of time and space provide principles of the real and the access to the experience of everyday life. Abstractions about childhood and learners, for example, are objectification activated by teachers as what is real in classrooms and the object of the knowledge and skills required for their professional expertise. The abstractions about teachers' communication skills in the models of teacher professionalism materialize as a universal and global knowledge for forming ways of acting and assessing immediate experience. This new knowledge is a reclassification, ordering and re-spatializing of the objects in which concepts of childhood and psychologies of development represent principles of the real phenomena actionable as learning.

It is not that humans did not use abstractions previously to reason about, for example, theology. What makes this quality of abstractions historically interesting and related to the political of modernity is that the categories and organization of phenomena embody a *homelessness* and *location-less logic* in which the classification and ordering the events of the present are taken as the origin of reflection and desires about human potentialities. The potentialities are about what should be and a comparative reason of abjecting the qualities about what does not “fit” in its normalized spaces. No longer life is organized through the time of gods and theology, *the abstractions function as concepts* that fix interpretive framing for how everyday life is lived, whether in Buenos Aires, New York or Shanghai.

This moving “away” and distancing produce the spatial representations and identities as a particular exterior designed to project and activate an interiority as the pedagogical objectifications. The classifying of the child as motivated, problem solving, self-actualizing and engaged are designed to order the interiority of the child—the soul. The concepts, however, appear as analytical distinct, folding into an ontology of the child as an exteriority of the objects of teaching and childhood. *The distinctions about learning form as the outside/surface/exterior is where design and installation of pedagogy happens.* The design of the surface projects its mastery over communication processes and classroom activities to an imagined, invented interior of the soul that is no longer named as such but as “the learner”, “mindsets”, and learning.

The concepts become determinant categories that deterritorialize the immediacy of experiences into abstractions and deterritorializes experience into concepts as the natural properties of the child (childhood), the school “context” and the pedagogical content. With the mind as the intermediary, the concepts of the child, learning and the curriculum serve to generate principles shaping and fashioning what matters as the spaces of action in the classroom. While *the concepts are given as representations of the objects of the world, they are intricately bound with the conditions that give intelligibility to the knowledge organized to change social life and people.*

The homelessness, however, works materially to produce “homes” of belonging and identities through the pedagogical practices of the school. Importance about these homes in the homeless reason for critical theory is the inscriptions of a comparative reason. The homeless, paradoxically, inscribes norms and rules about the borders of the normativity that excludes and adjoins particular kinds of people; qualities outside of the rules and standards of reason and bandished as in unassimilable spaces to which subjects are bound. This double qualities of potentialities radically exclude through the comparative reason that differentiates, distinguishes and divides capabilities and capacities of people. The abstractions about childhood and learners, for example, locate oneself in a broader world not accessible in immediate experience yet provide principles to experience “motivation”, “creativity” and the mundane practices that racialize and differentiate the body as lacking motivation.

This paradox of double gestures that exclude and abject in efforts to include are historical lines in the interstices of contemporary schooling, and the epistemologies of equality/inequality. Change today speaks about social and educational reforms as changing the “mindsets” and “habits of the mind,” providing “the funds of knowledge” and making the globally competent citizen, the professional teacher, and “the lifelong learner.” These kinds of people inscribed in contemporary teacher effectiveness and models of school improvement are anticipatory, a modeling of institutional life directed as normalizing practices to enable personal happiness and the betterment of society. The notion of change are salvific and redemptive, desires about the potentialities of the literate child that stands in opposition to the child left behind.

The increasing significance of the comparative reasoning of statistics and numbers embodies this homeless-ness and location less logic. The statistical measures and algorithms are fabrications that reclassify and reterritorialize everyday life and traditions through technologies of distancing and representations. Statistical measures perform seemingly without any historicity. Numbers standardize and calculate events and people as centers of calculation or observation decks for seeing, thinking and acting on the phenomena of education as a location-less logic to order “what matters” in schools.

Yet what is taken as the real and the origin of reflection and action through data points create new phenomena for thinking and acting about people and the future potentialities (Popkewitz, 2018). Pedagogy is the reterritorialization of life that creates new phenomena in a temporal order directed to the future. This desired future is expressed, for example, through notions of action, problem-solving and development. The classifications become focal points for what is real and comparative for the precautionary and preventive actions governing social life.

The distancing and location-less quality of modernity is not necessarily bad but continually dangerous. Modern science, as Daston (2011) explores, requires this homeless and location-less logic of abstractions, a process that involves learning to “see” and record events and things through abstractions organized in systematic notes that occurs between the 1600s and 1800s. In the sciences and practices of pedagogy, the homeless-ness and location-less logics are continually inscribed in a comparative reason.

The linking of the child with family and community generated principles as boundaries of inclusion and exclusion in an inscription of the moral order. The moral order (and disorder) affectively overlap with collective notions of “civic virtues” and “the common good” that generate its Others outside its boundaries of normalcy.

The question of a critical study of education being raised in this discussion is bound to the epistemological principles of difference embodied in contemporary reasoning. Our focus has been on the representations that act as identities located in a continua of values generated in the affective and cognitive structuring-the onto-epistemic principles- of schooling. The continua of values proceeds from some notion of sameness, embodied in the distinctions that differentiate in a manner in which the representations normalize and divide the qualities of people. The divisions are embedded in categories and ordering principles that represent identities in the curriculum, institutions, and social and psychological theories of schooling.

Critical studies

Our task joined critical theory’s complicated and ongoing relationship with the Enlightenment. We reference the notion of coloniality in our discussion to recognize the entanglements and multiplicities of forms of knowledge, affect and being in the enunciations of schooling as the disavowing and absorbing of differences (see [Mignolo, 2013](#); [Sobe, 2013](#); [Sobe and Kowalczyk, 2018](#); [Zhao et al., 2022](#)). The comparative reasoning of differences and specifically systems of differentiation presume utopic vision of progress and the future mediated and woven into a sameness as the art of government. The comparative reason has a materiality, articulated as “diversity” in policy, research and school programs that unify and coordinate differences within the normativity of the subject.

This recognition of the political and power embodied in the comparative reason of school has different coordinates, relations, and value to certain peoples/societies while disenfranchizing others as the infrastructures of schooling and its practical sciences settle in different historical spaces. Phrases like Eurocentric elide the varied and multiple settlements and the activations of desires and expectations about experience and futures. Social science traveled to China in the late 19th century, for example, as an agency of Enlightenment. Produced were lens of visualization and grids of intelligibility that colonized notions of reason, freedom and equality to elide any pre-existing thoughts and practices among the Chinese ([Huang, 2022](#)). This particular historical settlement of universalized reason and modernity re-territorializes China into a field of Truth that privileges a particular historical notion of humanism as an agential freedom of “becoming” over *life*.

The potentialities generate double gestures about the kinds of people excluded and abjected the “urban” populations of the turn of the 20th century and again the 21st century as urban populations who “lack” self-esteem, engagement, grit, and motivation-people and families abjected as being outside, as being consigned to unlivable spaces ([Popkewitz, 1988/2017](#); [Popkewitz et al., 2017](#); [Kirchgasler, 2016, 2018, 2019](#)).

The representational reasoning in the infrastructures of schooling and its sciences conceptually and physically banished populations as not being of *the average*. The objectifications that represent and identify differences cast out kinds of people who are made as strange, “foreign,” racialized, and as endangering the future. The principles of comparison reside in the distinctions and differentiations around who is to be, but its “others,” who does not fit into these spaces of normalcy.

If we return to our earlier discussion, today’s representations of critical theories have expressed and privileged the intersectionality of race, gender, ethnicity in Anglo-American literatures but within the onto-epistemic framing that conserves its specializations.¹⁰ Stabilized are the globality of space and regularized time that are distributed unevenly in the global order through a spectrum of state critiques and postcolonial literatures. Haunted by the shadow of Enlightenment related to Cartesian and representational logics, educational reforms are globalized, and often articulated and transcoded within salvific and redemptive logics and desires of the emerging nation-states and local intellectual production.

While haunted with shadows of the European Enlightenment, our discussion recognizes both its singularity and also the multiplicities of connections, assemblies, and disconnections in manifold historical spaces (see, e.g., [Zhao, 2018](#); [Popkewitz et al., 2014](#); [Popkewitz, 2022b](#); [Wu, 2013](#)). Important to the Enlightenment ideas of progress was its critique, the continual asking of how we have arrived at the present and its limits as a method of the possibilities of who we are, who we should be, and change. Critique is to cut into the causalities of the present to make fragile what seems inevitable, cutting into what seems self-evident to give historical contingencies to objectifications and the ontological determinism. To return to Foucault, criticism is a matter of flushing out what is thought and trying to change it: to show that things are not as self-evident as one believed, to see that what is accepted as self-evident will no longer be accepted as such.

Critique of *difference* is to hold open possibilities outside of contemporary frameworks that inscribes differences within the unity of oneness. The historicizing focuses on the contingencies of what would otherwise be taken as the unquestionable objects of thought, action, and change.

As [Deleuze \(1986/1988\)](#) and Foucault argued in the 1980s with an indebtedness to the attitude of the Enlightenment, if not contemporary dogma, critique is the diagnosis and the dermatology of apparatus which power installs on the surface of our being. It is to crack things open yet does not stop where the previous grids of intelligibility are ‘destroyed’ or replaced with a new one. It is not to mythologize power but to make visible the internments, enclosures and forces being produced so as to make possible alternatives.

The strategies of critique we believe are entangled in the spaces of a range of critical studies associated with scholarship in the “posts”, queer and de-colonial literatures. The critical impulses are to resist the spaces of normalization, differentiation and abjection in its concreteness that are never merely “of schooling.”

The engagement in critique is an optimism about the possibilities of change. That optimism about change lies in making unstable what is taken as natural, “bound up more with circumstances than necessities, more arbitrary than self-evident, more a matter of complex, but temporary, historical circumstances than with inevitable anthropological constants” (Foucault, 1988, 156). It embodied an optimistic suspicion of the present. To borrow from Stoler (2016),

Critique here is not about “fault finding” and judgment but about restoring the forms that occlusion takes and the questions that its effects may lead us to ask. Thus, the effort is to understand that occlusion is an ongoing, malleable process, sometimes in a form already congealed and seemingly over as it acts on the present, making of us unwittingly compliant observers, nearly always belated in identifying just how it works. (p. 14).

The testing the limits of the present does not give up notions of freedom and agency. Agency, as explored here, lies in challenging the habitual ways of working and thinking in constituting society and people. This challenging of the habitual ways is “grasping for freedom and liberty” by historically exploring the “practical test of the limits that we may go beyond, and thus work carried out by ourselves upon ourselves as free beings” (Foucault, 1984, p. 47). Agency can be thought of as testing the limits of the present, freeing ourselves from the particular dogma of the present through a resistance to what seems inevitable and necessary.

Reflecting on critique as an agential power is to examine how life is divided, measured and produced as onto-epistemic forms of universal reason and progress. The freedom of agency is not the “intrasection” of agential power by projects of making kinds of people and making the body and “soul.” Critique is to open up collective spaces of action that are not directed to phantasmagrams of the prophetic future but to affirm immanent planes of life and potential art of resistance.

In the academic world, “theory” refers to a system of research-based statements that serve to explain parts of reality and its underlying regularities. These explanations often make timeless claims, not least because the research process is characterized by “reliable” and “valid” methods that were developed to describe the actual factuality of this reality, i.e., to generate “objective” knowledge that is strictly separated from and unaffected by the inevitably contingent researching individual (“subjectivity”). Initially developed between the seventeenth and nineteenth centuries for those sciences aiming at discovering natural laws, this model of research began to oscillate around and after 1900 more and more into the exploration of human practices. Armed with an arsenal of this kind of objective knowledge, interventions in social and thus educational realities became more legitimate (“evidence-based”), and ultimately these interventions upstaged negotiations of different views and opinions. These developments paved the way to what can be called “expertocracy” as an alternative to (too much) democracy.

Under these assumptions, theoretical progress has always been interpreted either as a correction of older attempts at explaining parts of reality—a phenomenon to be witnessed often in philosophy or history of education—or as a supplement to them, leading to a more precise or more in-depth explanation—as we find more often in psychologically based research in education. The first case is about the falseness of previous research; the second case is about (as a silent rule) confirmation and differentiation. In both cases, however, new research is performed to formulate theories describing parts of social reality in a way that “adequately” or “objectively” defines a possible necessity and strategies of intervention. In the broad field of all social sciences, there have been few disciplines that have not only quickly placed themselves at the service of these interventionist motives but have also sprung directly from interventionist aspirations as research in education in general and curricular research in particular have done.

In the different histories of science, of knowledge, of theory and even of education as an academic discipline, however, there is no theoretical agreement among the approaches defining the research objects, the research methods and the theoretical insights resulting from the respective research activities in the different research institutions across the world. Rather, we are faced with quite different epistemological configurations of theories which, although they do indeed move internationally, morph in the process (Cowen, 2009, 2021), and they can usually hardly discard the normative premises from which they originated. Accordingly, in order to understand the meaningfulness of their statements, insights or theories, these normative premises must be sought, excavated and understood, an approach for which the concept of archeology is often used (Foucault, 1969; Pocock, 1987, p. 23). It leads to the discovery of different—I call it that way—cultural milieus that are composed of two fundamental and often intertwined normative systems of thought related to the making sense of the world: religion or denomination on the one hand and the nation on the other. Both of these systems of thought are often understood as discourse, discursive formation or *langue* (Billig, 1995, p. 8; Calhoun, 2007, p. 3; Özkirimli, 2010, pp. 206–217, Tröhler, 2011).

Following the basic assumptions of the linguistic and cultural turns in the social sciences, the appropriate attitude or answer to this plurality is obviously not the search for a more comprehensive meta-theory, but it is the understanding of how religious-national or denomi-national cultures each generate different perceptions of what a problem is that is in need of being addressed and accordingly formulated with different (research) questions, which usually entail different research methods, and which, not surprisingly, lead to different kinds of theories. This cultural milieu-sensitive understanding of plurality in both everyday and scientific production of knowledge and theory as different ways of making sense of the world cannot but be historically and comparatively informed. Yet, only few committed researchers and activists in the field of education in general and in curriculum studies in particular are committed to wider historical reconstructions, either because they share an understanding of historical research as dealing merely with a past that no longer has any relevance to today’s challenges or because they want to prevent the usually hidden value limits of their own perception of these challenges from being historically reconstructed. Just as theory traditionally claims to be independent of time, one wants to be “objective” as an actor in the definition of the need and the formulation of theory. These claims are made as if Ludwik Fleck’s ideas of “thought styles,” which are supported (and defended) by “thought collectives,” had not been formulated over 80 years ago (Fleck, 1935/1979), explaining how particular “styles of reasonings” (to refer to Ian Hacking, 1992) arise and are cultivated and handed down in—usually—national associations, which in turn act as powerful gatekeepers in academic journals, academic book-series and thus in academic careers (Tröhler, 2020a).

In contrast to these claims, it seems evident that theories are inevitably historically bound expressions of particular ways of thinking about and making sense of the world, and as a rule they fight for recognition and supremacy. Some, then, become dominant, others regressive, and even if in the historical process they have had an impact on each other, they are not or are

only partly traceable to each other. This is also true, and particularly so, for curriculum theory, which has emerged as a distinct genre or sub-discipline of education above all in the Anglo-Saxon-Protestant milieu and has had, and still has, difficulties in establishing itself as a globally recognized research field, especially on the European continent. This is so for good reasons that can be recognized historically by discovering that the object of research, “curriculum,” is a very specific, and not universally shared, perception of what school should be (doing) in the context of a given society. “Curriculum” is not simply a word that could be translated arbitrarily, but a *parole*, whose meaning it takes from a particular *langue* or normative thought system in the making sense of the world. This being said, “curriculum” is, for instance, something different from the German *Lehrplan*, even though most dictionaries would translate *Lehrplan* into curriculum, and vice versa (the literal translation of “curriculum” is the “plan of teaching” or the “plan of what should be taught”) (Horlacher, 2018). This plurality, already even in the object configuration, makes research incredibly diverse and comparative international cooperation for the purpose of clarifying theory building rather challenging.

The following article attempts to analyze this complexity of curriculum and to reflect on what this means for curriculum theory in four steps. First, the history of the development of curriculum studies as an educational sub-discipline is reconstructed in its specific cultural milieu characterized by particular ideological preferences which became heavily contested in the last third of the twentieth century (1). In a second step, an excursus into the early seventeenth century demonstrates that “curriculum” is associated with a specific denominational religious interpretation of the world and that another religious system contained an idea of education and learning of its own, which was then called *Didaktik*, which differed substantially from “curriculum,” and with which *Lehrplan* was later associated (2). Building on this, the third step shows how these different models became nationalized during the long nineteenth century and were thus understood as an effective means of educating loyal, national citizens in the respective contexts and that this nationalization affected not only schools but also science, both of which are shaped by national epistemologies (3). In a final step, there is a reflection on how research can deal with this institutional and epistemological plurality, and, on this basis, three different theoretical models are formulated, the most comprehensive version of which is tightly connected to a comparative educational history (4).

Curriculum studies: the cultural configuration of a sub-discipline of education research

In the beginning, when research began to deal more systematically with “curriculum,” there was no such concept as “curriculum theory.” One spoke of research activities by using “curriculum inquiry” or “curriculum studies.” These terms date back to the early 1900s, when the United States was faced with the challenge of a massive mass immigration of people who came from countries that were culturally very different from the more or less established national and political culture of the United States (or at least of its cultural and political stakeholders). Since, in the United States, the content of teaching in schools was defined by the individual school communities and locally acting superintendents—and not centrally or at least regionally, as in most parts of Europe—there was or seemed to be a considerable need for academic support to adjust the curricula to the perceived challenges of the local schools.

A first overview of these various studies and inquiries about curriculum reform was published by the Canadian-born Werrett Wallace Charters in his 1923 book *Curriculum construction* (Charters, 1923). None other than one of the main representatives of the so-called social-efficiency-education movement, John Franklin Bobbitt, arguably the first “star” of curriculum construction in the United States, reviewed Charters’ study under the title *The technique of curriculum-making* (Bobbitt, 1923). Thereby, Bobbitt assumed that the professional field in education, which had hitherto been satisfied with rather vague assumptions about the objectives of school education, “has been growing dissatisfied with prescientific methods of guessing at the objectives of education” and has therefore “undertaken the task of scientifically determining its objective” (p. 787). Bobbitt identified Charters’ book as a kind of meta-analysis, by which he honored the author—inexplicitly—as the founder of academic curriculum study, for the book “summarize[s] the results of the many investigations of the past decade and present[s] in systematic form the theory and the technique of curriculum investigation” (p. 787). Hence, the “book is obviously written for scientific investigators in the field of education and for students of the technique to be employed” and precisely “not written ... for the purpose of guiding the practical superintendent in his immediate labors of formulating a curriculum in its totality for next year’s work” (p. 788).

The translation from or implementation of theory into practice, that is, of scientifically identified technologies into the practice of local school authorities, had become part of Bobbitt’s lifetime commitment in the context of an industrializing economy and its alleged social needs (Bobbitt, 1918, 1924), and by far the most famous publication on this subject, *Basic principles of curriculum and instruction*, was published by Bobbitt’s like-minded fellow, Ralph W. Tyler (1949). The “science-based” proposals formulated therein presupposed both the psychological scientism in education, which had been cultivated above all at the University of Chicago and at the Teachers College in New York, and the American characteristic of adapting the curricula locally and from year to year. In a rather intriguing way, Tyler’s *Basic principles*, which aimed at giving advice to local policy makers acting in a unique national characteristic of the radical local principle in school organization, was then praised as a universally valid rational method of problem-solving in education.

Hence, what characterized curriculum studies or curriculum theory in the first 50 or 60 years of its sub-disciplinary existence in education was a very specific concept of cooperation between scientific expertise and school policy on the one hand and a school political reality that was extraordinarily, strongly localist on the other. It represented a political, psychologically based epistemology that was strongly influenced by conservative Protestant, often Presbyterian, circles and aimed at helping a political school reality that was greatly shaped by Congregationalist Protestantism, which was placing communal autonomy at the center. Tyler, who had in fact

once wanted to become a Congregational missionary to Rhodesia (today's Zimbabwe) and who had always professed himself as belonging to the conservative circles in the Congregationalist Church (Tjerandsen and Chall, 1987), made, then, an excellent career in countless committees as a scientific advisor or expert of school policy, which, especially in the post-Sputnik era of the United States, expanded globally almost in a missionary style via the expertocratic culture of the OECD (Tröhler, 2014).

However, in the course of the 1960s, strong intellectual and political-agitative opposition arose against this concentrated charge of system-stabilizing conservative WASP culture (not only) in education, which was later subsumed under the term "reconceptualist movement." In 1977, B. J. Benham and Billy Askins published a literary review with 50 annotated studies identified as part of this *Reconceptualist movement* (Benham and Askins, 1977). The notion of "movement," here, might perhaps be misleading, as one of the authors noted, as it lacked an "organized structure." In addition, he stated that "it is a fluid coalition of individuals who share a similar conceptual frame-work and value system, and who object to the mechanistic production metaphor that predominates in American schooling at this time" (p. 3). Some of the proponents of this movement were neo-Marxists, some democratic socialists, and, a little bit later on, some of them were Foucauldians or they were a blend of these ideologies. One of the first major exponents of this movement, William F. Pinar, remembered later how he and his combatants rejected the traditional role of curriculum and curriculum research in the United States (Pinar, 2004, p. 209):

... the official or institutional curriculum (especially the secondary school curriculum) was settled, more or less, during the early 1960s; it would be directed toward and articulated with post-secondary destinations, primary among them the university and the workplace. It was—and remains—a gendered and racialized rite of (academic) passage. By the early 1960s, what remained of the progressive dream—education for democratization which meant schooling for psycho-social as well as intellectual development—was past.

In this movement, among others, the term "hidden curriculum" became a pejorative battle term. First, it was used in the early 1960s to describe social learning processes in the classroom that were not defined in the formal curriculum:

There is a hidden curriculum in every school which teaches, in addition to reading, writing and arithmetic, how to get along with one's fellow-man and how to think about and evaluate oneself and others ... each student is pressed to conform to the kinds of attitudes, beliefs, mores, and behavior which surround him

Pinderhughes (1964/1966, p. 2196), see also Jackson (1968), Overly (1970).

During the 1960s, this term became one of the centerpieces of the "reconceptualist movement" as it served to expose the capitalist-conservative, and therefore *eo ipso*, unjust system which was exemplified in questions of race, religion, women, migrants and workers (e.g., Apple, 1971; Snyder, 1971). As a research "product," theory should not focus on providing efficient advice to the local stakeholders but reveal the disciplining and oppressive mechanism of the U.S.-American curricula and provide advice and inspiration for more individual or collective creativity, freedom and justice. Out of this movement, the *Journal of Curriculum Theorizing* emerged in 1979, and the first issue included lead articles written by, among others, Michael W. Apple (*On analyzing hegemony*), Janet L. Miller (*Curriculum theory: a recent history*) and William F. Pinar (*What is the Reconceptualization?*).

The activists of this movement have triggered an impressive, but also very diverse, intellectual development in the field of curriculum studies, which has found numerous international collaborators and supporters, especially in those countries that traditionally had close ties with the United States. Notwithstanding, this movement has not fundamentally changed the field of curriculum research or theory to "their favor," but they have broadened it in a sustainable way. Today, curriculum studies—after all, a prestigious division of AERA since 1964—represents an extremely heterogeneous field of research whose original motives, namely research-based policy advice, are still prominently advocated today, even in an explicit polemical rejection of the "reconceptualist movement" (Deng, 2018). However, this internationality disguises the fact that it is nevertheless a relatively one-sided phenomenon, not with regard to what has sometimes been called "developing countries," but at least in particular with regard to Europe and more precisely to Central and Northern Europe. It is not that researchers in these areas do not care about school or the content and skills to be taught in the classroom, but they do so based on a very different understanding of schooling and the organization of teaching and learning. These differences emerged from competing religious cultures that, although in various ways, emphasized the role of education with regard to salvation.

Denominational roots of the cultural configuration of "curriculum" and "Didaktik"

In the 1990s, an international, or at least transatlantic, collaboration discussed the nature of the Anglo-American curriculum tradition as compared to the German *Didaktik* tradition (Gundem et al., 1991; Gundem and Hopmann, 1998; Hopmann and Riquarts, 1995; Doyle, 2017; Sivesind and Luimes, 2017); interestingly, and not coincidentally, as will be shown, the notion of the *Lehrplan* was not included in this comparison. The initiators of this collaboration spoke of "differing attitudes toward curriculum planning and implementation," as the Anglo-American curriculum tradition would build on "method-centered teacher education" and act in local environments, and the German and Nordic *Didaktik* tradition and its teacher education would build on content and operate in a "centralized education system with state control over curricula and syllabi" (Gundem and Hopmann, 1998, p. 1). What made the

conversation particularly difficult, the initiators held, was the fact that the central concepts and terms of the German and Nordic tradition lacked “counterparts in English,” as for instance *Didaktik* or *Bildung* (p. 2)—but the same would of course also apply in the other direction since “curriculum” is not simply “*Lehrplan*,” even if dictionaries would suggest so.

Looking at this phenomenon or challenge of translation from the perspective of the linguistic turn, one can take this phenomenon to a deeper ideological level by, following the suggestion of Ferdinand de Saussure or John G. A. Pocock, understanding these terms as *paroles*, each of which gets its own meaning from a particular *langue* (Tröhler and Horlacher, 2019). It then turns out that the difference between curriculum and *Didaktik* lies on a very fundamental religious-ideological level which is characterized by two different Protestant traditions: the Swiss-Reformed on the one hand and the German-Evangelical on the other. They express a fundamental cultural difference in the construction of curriculum and the perception of subjectivity, which Tero Autio already indicated in 2006 (Autio, 2006). These differences become apparent in one of the first conflicts that arose in the context of schooling and learning, namely, in the example of Johann Amos Comenius and his didactic conception, i.e., in the beginning of the seventeenth century. In this time, there was a generally intense discussion of learning and knowledge that developed between Bacon’s *The advancement of learning* (Bacon, 1605) and Comenius’ *Didactica Magna* [Great didactic], the most famous part of his *Didactica Opera Omnia* (1657). Obviously, most of these discussions took place during one of the greatest tragedies in European history, the Thirty Years’ War (1616–1648), and it included, foremost, Protestant scholars from England, Northern Germany and Moravia (today’s Czech Republic).

While in England an early empiricism fostered an idea of learning, research, new knowledge and progress also for the benefit of the people, an attitude which was reflected among other things in the foundation of the Royal Society (1660) (Tröhler, 2020b), German thinking was caught up in religious idealism in so far as it was assumed that all relevant knowledge had already been given biblically and that it was only a matter of teaching it in an appropriate way. It was the intersection of the emphasis on method, as promoted by Bacon (1605), and on absolute biblical authority that lead the German Lutheran Wolfgang Ratke to the creation of the notion of “*didactica*” after 1610 (Knecht, 1984, pp. 102–104). Didactics was therefore a matter of bringing the spirit of the Lutheran Reformation and the authority of the Bible into schools. Accordingly, Ratke promoted German lessons at school on the basis of Luther’s translation of the Bible as the prime school subject. Apparently, this idea of *Didaktik* was what the Lutheran audience in Germany had wanted, for the concept of didactics spread at lightning speed and had become so popular (and correspondingly ambiguous) that even Comenius could not escape it (Knecht, 1984, pp. 107–108).

Comenius, who was a member of the Protestant Bohemian-Moravian Brethren Unity—actually a third alternative to the Swiss and German Reformation, but with much less success in its institutionalization, had been on the run since 1620 as a result of the Thirty Years’ War. He began to write, from 1626 on, an educational treatise that was only completed years later and published in 1657 in Amsterdam: the *Didactica Opera Omnia* (Comenius, 1657). In 1638, he sent a draft version of it to Joachim Hübner in England, who belonged to the *Hartlieb-circle*, named after the Protestant activist Samuel Hartlieb and to which, for instance, the Scottish Presbyterian John Dury belonged. This *circle*—a precursor of the Royal Society—was often called the “invisible college” of pansophic Protestant activists with strong educational aspirations among whom knowledge was created, collected and exchanged, and even designs for calculating machines, double writing machines, seed machines and siege machines were distributed. They helped persecuted Protestants on the Continent, and they tried, in the end unsuccessfully, to convince Comenius to move to England permanently. Hübner’s response to Comenius’ request for feedback of the draft version of *Didactica Opera Omnia* (Comenius, 1657) reveals the fundamental difference in the understanding of the basic question of schooling, teaching and learning, for Hübner criticized Comenius’ major ideas as belonging to the “didactical sect” by which the rules of teaching were elaborated completely free from any content to be taught, and that, therefore, was in fact senseless (Hübner, 1639/1898, p. 81). This reproach is essential and deserves a closer look.

In the published version of *Didactica Opera Omnia* in 1657, the content of teaching was defined in the most famous part, the *Didactica Magna*. It was, simply, everything, as the subtitle of the *Didactica Magna, Universale Omnes Omnia* (The whole art of teaching all things to all men), indicates. In principle, this included everything that one understands as the object of “curriculum studies”: the learning content (all things), the addressee (all men) and the type of teaching (whole). The defined learning content was divided into the three areas of science, good morals and piety. Comenius’ religious conception of man is optimistic, and, therefore, the mediation between content and addressee—that is, teaching—should be, as Comenius said, “quick, pleasant and thorough” (*compendiose, jucunde, solide*). Built on these principles, Christianity would contain “less darkness, confusion and dispute, but more light, order, peace and quiet” (Comenius, 1657, pp. 15–16). Why, then, had the empiricist Hübner been complaining that Comenius had elaborated rules of teaching free from content?

It was Comenius’ deepest conviction that—anthropologically speaking—man, by his very nature and in spite of his original sinfulness, has within himself all the capacities for good and that by means of didactics he brings out this goodness by educating himself in scholarship, virtue and religion (*Eruditionis, Virtutis, Religionis*) (1657, p. 31). Since man is understood as a microcosm of the (divine) universe, didactics does not mean to learn new things (content) that come from “outside,” but to “only evolve” (*solum evolvi*) what is already given in him by his divine descent (1657, p. 32). Comenius’ understanding of didactics thus implies the process of consciousness-making of divinely predetermined things in a universal cosmos. This conceptualization differs fundamentally from an understanding of learning that the science-oriented Reformed Protestants in England pursued. Admittedly, none of these English exponents of empiricism doubted the divinity of nature, not even Isaac Newton, but at most, they took the order of this nature as the starting point of an inductive empiricism without understanding man as a micro-cosmologic mirror of a divine universe.

While the German Lutherans subsequently thought of the idea of progress—popular everywhere in the course of the seventeenth century—strictly inwardly in the human souls as a development process toward the image of God and his creation, the English Calvinists thought of progress scientifically and thus technically and ultimately socially (Tröhler, 2017). In the Calvinist milieu, with its mission to shape God's kingdom on earth, progress had to be approached in an organized and orderly manner, and, in the field of education, it was the term “curriculum” that was used precisely for this purpose, first, already in 1582, at the Calvinist University of Leyden and then in 1633 at the University of Glasgow (Hamilton, 1980, pp. 12–15):

From this perspective there is a homologous relationship between curriculum and discipline; curriculum was to Calvinist educational practice as discipline was to Calvinist social practice (p. 14).

During these decades of the late sixteenth and seventeenth centuries, a reservoir of ideas was created that was implemented in the establishment of the school system and updated exactly when it was believed that the school would no longer be able to properly fulfill the tasks set in it. Hence, better organization of learning and discipline were conceivable as organizational principles when, at the beginning of the twentieth century, the United States faced the question of how to deal with migration and the social consequences of capitalism. This orientation toward discipline or disciplining subsequently favored, especially against the background of crisis perception, an increasing sciento-methodological orientation that should lead to a certain standardization of the localist school reality in the United States, thus promising the empowerment of future citizens building a godly future. Conversely, in the German tradition of reading and receiving Comenius' work, teaching and learning were less about a strict adherence to curricularly defined content and more about the—according to Comenius, free, pleasurable and progressive—spiritual appropriation of the sacred world. After the aesthetic turn of Lutheran thought in the eighteenth century, this appropriation was called *Bildung*, the harmonious inward perfection of the soul. This tradition was never about knowledge per se, but about godly wisdom that transforms the individual soul of the human being as a human being, while the other, Anglo-American tradition is about curricularly defined knowledge, the transmission of which is removed from chance so that the citizen was formed to transform the world. “Curriculum” represents an idea of method, learning and controlled empowerment, whereas *Didaktik* indicates the appropriation and aesthetic of *Bildung*. This is exactly what perhaps the most prominent European representative of the curriculum-didactics debate in the 1990s meant when he wrote that his didactic concept was influenced by German *Geisteswissenschaftliche Pädagogik* (Klafki, 1998, pp. 307–309, 312–314), a deeply Lutheran discourse of education (Tröhler, 2003) that never aimed at knowledge empowering an “atomistic individual”—this had been the standard accusation of German Lutheran scholars against the political culture of the United States since Max Weber (Tröhler, 2011, pp. 42–49)—but that aimed at the empowering of the “connection of the individual to the general” (Klafki, 2000, p. 93) with the aim of “fundamental reasonableness, to concrete universality” (p. 92).

Against this background it becomes understandable why the term *Lehrplan* has hardly appeared in the mentioned transatlantic collaboration discussing the nature of the Anglo-American curriculum tradition as compared to the German *Didaktik* tradition. Facing an envisaged universality and *Bildung*, the aesthetic transformation of the soul, questions of curriculum as *Lehrplan*, of deciding what knowledge and skills should be taught to future citizens, have hardly played a role. *Lehrplan* or *Lehr-Ordnung*, did not even exist before the second half of the eighteenth century; the first use of the term *Lehr-Plan* is interpreted as the commission of Jesus to his disciples (Hanauische Berichte, 1751). Accordingly, research on *Lehrplan*, that is *Lehrplanforschung*, played, in the context of the Lutheran countries in Europe, at best an extremely marginal role.

National curricula and national epistemologies

While today the terminologies have (almost) lost their religious obviousness, the Protestant reflex to entrust not only all kinds of social problems but also the imaginaries of the self, the world and the future to education has (almost) become a global matter of course (Tröhler, 2016a). Discursively, though not obviously terminologically, educational and curricular thinking are religiously shaped. However,—to add theoretical complexity—since the long nineteenth century, this thinking has been configured and sacralized more and more in the context of what has been called nation-building, i.e., in the context of the nation-states, which have been both sacralized and educationalized and have thus acted as the answer and countermovement to what is called (institutional) secularization.

Since the beginning of the early modern age, when we find the first more or less coordinated attempts at educating the masses of the inhabitants of the different political entities, the business of school education has been more than simply teaching the skills of reading, writing and, at best, arithmetic, but it has been about making children become a certain kind of person, i.e., good Christians, depending on how “good Christian” was defined in each case. In the Age of Enlightenment, which can be dated as beginning in the middle of the seventeenth century, there were first reflections on and reforms of modern academic elite education in the English Commonwealth. Then, around 1700, there were broader educational reforms for social outsiders, mostly in cities of Protestant Europe (children of poor or delinquent parents, orphans), and later for the urban citizenry and then deliberately of political leaders. All these educational conceptions had different ideas about the form, content, mediation and aims of education, and from this huge repertoire of educational conceptions developed during this Age of Enlightenment, the emerging nation-states of the long nineteenth century, triggered in the wake of the French Revolution, were able to be selective in order to turn their inhabitants into loyal citizens (Tröhler, 2016b, 2020b).

Although the relationship between nation-building and education is considered important for research on nationalism, it remains completely under-researched, just as the topic is largely ignored by educational research in general and curriculum research in particular (Tröhler, 2020a). Yet, modern constitutional states have depended on the loyalty of their citizens, which is promoted by citizens identifying themselves with the cultural thesis called “nation,” *their* nation, whose characteristics and dignity they see promoted and defended by the state. The state has the privileged means of promoting this national identity, be it through its own transportation systems, television channels, stamps, currencies, work-free holidays, national teams at the Olympics and world championships, and the school and its curriculum or its *Lehrplan* in connection to *Didaktik*. In the school, we detect subtle practices of “doing nation” and the development of “national literacies” that allow citizens to recognize national symbols and flaggings as theirs as opposed to others (Tröhler, 2020c).

As at the beginning of the early modern era, school education has been about making a certain type of person into a morally loyal national citizen who is imagined quite differently in various places: No one would claim—then or now—that a French citizen (*citoyen*) is basically the same as a German citizen (*Bürger*), or a U.S.-American citizen as a Canadian citizen, and not even the Scandinavians, who claim to be part of a shared Nordic culture, have the same imaginaries when it comes to their national citizenship and identity (Hjerm, 1998; Kellas, 2004, pp. 126–137). Nationalism, as a national sentiment or identity, has to be learned somehow, as no one has been born a citizen. It is not with a single school subject that this is done, however, for civic and political education are not the same as educating the future citizens (Horlacher, 2020), but with a cross-curricular aim that not only concerns the more obvious subjects of history or geography but also includes, for instance, mathematics. As a rule, children learn national mathematics (Boser, 2020), and, since the foundation of the republic, a U.S.-American child does not simply learn the English language (how to spell, write, read) but becomes a U.S.-American by virtue of spelling, writing and reading (Bynack, 1984). Thus, even orthography could equally become a means of nationalization, as in the case of the Netherlands (Schoemaker and Rutten, 2019), the same as the struggle over typefaces being used at school (Boser and Hofmann, 2019). In these fabrics of educating the future loyal citizens, the same historical events become very different stories depending on which nation tells its future citizens these events (Gotling, 2020; Peckovic, 2017).

This adds serious complexity to curriculum research aiming at theory. One could perhaps still deal with this incredible plurality in the fabrication of loyal nationalities if one had a more or less uniformity in the perception of issues or if one had “only” to deal with curriculum and *Didaktik* as two (and there are probably more) fundamentally different ways of conceiving of the essence of schooling. But the epistemologies themselves not only have a dual structure corresponding to the various Protestantisms, they also have national connotations and attempt in complex ways to unfold hegemonic effects in an imperial manner (Fox, 2020). Of course, one can ignore epistemological differences by making one’s own epistemology absolute, and then it is easy to level out these national differences in curriculum and curriculum research and to explore the whole world according to the paradigm of the Anglo-American understanding of curriculum, coming to the conclusion of the advent of one “world culture,” a “world society” and a “world polity” (Meyer, 1980; Boli and Thomas, 1997) that create and result from a “world curriculum” of the “global village,” thereby indicating the “relative unimportance of the national, so far as mass curricular outlines go” (Meyer, 1992, p. 6). However, there is actually very little evidence for this, and certainly not in the contemporary age of coarse nationalism demonstrated by the very many (elected) political leaders on all continents of the earth. Rather, it seems that these theories are more results of a self-fulfilling prophecy (Tröhler, 2009) as they explain less a reality than they actually produce imaginaries that act as depicting reality (Carney et al., 2012, p. 368).

Against this background, it has been suggested to distinguish between “internationalization” understood as an “ethical engagement with difference” and “globalization” understood as “neo-imperialism enforced through economic and educational standardization” (Pinar, 2015, p. 36). With these terms, we are obviously dealing with a fundamental, epistemological challenge that has massive consequences for school policy and curriculum reform. It points to the core of the challenges facing curriculum research and curriculum theory.

National discourses, international research and curriculum theory

So far, two different theoretical models of the curriculum have been discussed and presented which are at different levels of theoretical abstraction. Before presenting a theoretical approach at a third, even higher level of abstraction, these two models will be briefly recapitulated. The first model of theory, at the lowest theoretical abstraction level, aims at an educational technology that is meant to be first developed and then applied, copied and pasted in the same cultural environments according to the doctrine of “what works,” even if international scholars have critically discussed *Why “what works” doesn’t work* (Smeyers and Depaepe, 2008; Biesta, 2007). Even though it is difficult to define this kind of knowledge as an academic “theory,” it must nevertheless be accorded a high degree of attractiveness, firstly, because it can be copied and is therefore inexpensive, and secondly, because it at least promises to implement research, which, to varying degrees, is always promising. Especially in the American idea(1) of social efficiency, this model has a certain plausibility, precisely because it is so closely aligned with the normative premises that had initially given rise to the idea of “curriculum” as a specific form of organizing schooling. This approach or attitude to research is very akin to a policy that does not want to “waste” time in negotiating too much but wants to be all the more efficient, as can be seen from an interview with the chancellor of the New York City Department of Education, Joel Klein, on March 9, 2008. In an interview with the New York Times, Klein told the journalist:

What you need to create ... is a school district that people from other cities can come to and say: “This works. All we’ve got to do is replicate this”
How many billionaires (2008).

It is evident, however, as the “reconceptualist movement” in the United States has criticized—and this critique indicates the second model of theory at a middle theoretical abstraction level of curriculum theory—that this kind of research and policy understanding of the first level does not seek to change the dominant notions of social order and good citizenship. On the contrary, it does not seek to question them, but rather to reinforce them. When the U.S.-American society of the 1960s became for many intellectuals an expression of falsehood, injustice, racism, sexism, oppression and exploitation that had to be fought, some of these indignant intellectuals turned their attention to the curriculum, developing this second model at a middle theoretical abstraction as they reflected the ideological bias of both curriculum and traditional curriculum research which represented the first level of abstraction. However, the discussion of this reflective approach representing the second level of abstraction remained largely within the normative realm that has characterized “curriculum” as a cultural institution and organization of creating future citizens. Hence, “curriculum” was not so much targeted by critics as a particular organizational form of institutionalized settings of teaching and learning at school, but rather for its normativity that preserves the social and political system. Certainly, there were demands that compulsory education should be softened, that the teacher-pupil relationship should be less hierarchical, that the school should not be selective and should place more emphasis on creativity, peacefulness and justice. A differently oriented curriculum should, in other words, by virtue of the normative power inherent in the organizational form of “curriculum,” create a different, more just society, one which is Marxist, socialist, democratic or freed from all unnecessary (or even from all) constraints. Today, after almost 50 years since the “reconceptualization movement,” the concerns are perhaps not less radical, but the forum of discussion has become less dogged. Marxist motives still play a role in curriculum criticism (e.g., Apple, 2001), as does the French post-structuralist inspired criticism of the idea(l) of the empowered self, which is tightly related to the traditional understanding of curriculum (e.g., Popkewitz, 2008). Still others have reformulated their commitment to plural democracy and seen in this context the “self-reflexive individual” willing to communicate with others as the goal of education and curriculum (Pinar, 2004, p. 224).

The sometimes astonishingly refreshing critical radicality of these theories of the second level can even be surpassed once again if they were to become less normative and more descriptive. This includes the epistemological emancipation from both the curriculum and the *Didaktik* traditions, which evidently want to—as all ideologies or discourses do—perpetuate themselves. This indicates a third level of abstraction in theory formation, which inevitably becomes historical, comparative and international, and it needs to be contextualized in a broader context that starts to see education in general as a medium of salvation. At least a first essential step has been undertaken by Pinar in his *International handbook of curriculum research* (Pinar, 2014a), in which curriculum research in 34 countries are described (in 39 reports), some of them written in light of the “reconceptualist movement.” In his own introduction, Pinar attempts to de-culturalize the connotations associated with “curriculum” in order to give the developments and traditions in the different countries the right to present themselves from their own ways of thinking (Pinar, 2014b). “Curriculum” thus necessarily becomes a “floating signifier,” a formal concept that is materialized everywhere, similar to the concept of the citizen. The close relationship between “curriculum” and “citizen” points to the logics of the nation-states in which previously developed educational aspirations and ideas of salvation were organized and instrumentalized by state authorities to strengthen the countries in several respects (Tröhler, 2019). Hence, the concrete organization of schools, their formal architecture consisting of levels and tracks and transition regimes as well as their curricula, textbooks and kinds of teacher training are thus a national configuration of educational concepts that are much older than compulsory schooling itself.

A curriculum theory of this third level of abstraction—transcending the second level of theory formation (the “reconceptualist movement”) that, itself, criticizes the service providers of the first level of abstraction in theory formation—therefore takes into account the powerful motives behind the development of modern compulsory education and the entire educational system, which are both religious in their origins and national in their configurations. They are manifestations of what is labeled as educationalization, not only of social problems and challenges (Smeijers and Depaepe, 2008) but of the world and of the modern self (Tröhler, 2016a). In this context, it is no coincidence that the modern self, which has become a major educational project, is worked on from birth to the grave, as first prominently described by Jean Calvin. In his major work, *Institutes of the Christian religion*, Calvin (1536) states in the very first two sentences of the first article that all wisdom, deserving the name of wisdom, consists of two parts, namely the knowledge of God and the knowledge of ourselves, and that they are interwoven in such a way that it is impossible to decide which knowledge results from the other (Calvin, 1536/1823, p. 1). The self, in this Reformation view, has a duty to be conscious of the Christian doctrine, and a large number of strategies of enforcing self-reflection, such as diaries (Blaak, 2009), have subsequently become media of Protestant self-assurance. Reading and writing thus became prominent cultural techniques with the aim of educating the religious person, of forming the religious self. They were often combined with singing, and only later did arithmetic come into play because this religious self had to be able to calculate in the transformation to an industrial society (Cohen, 1999). As a national self, history, geography or even gymnastics had to be learned and incorporated (Tröhler et al., 2017).

Curriculum theory of this third level of abstraction historically traces religious motives and how they were educationalized and then brought into the organizational form of the school, where they shaped what can be called “curriculum.” The global dissemination of these educationalized models of salvation, which grew out of originally Protestant concerns and ambitions, and how they changed over space and time and became nationalized in the long nineteenth century have certainly not yet been sufficiently researched in an internationally comparative way that respects the different idiosyncrasies in the performativity of the different school systems. There is a need for archaeological reconstructions of how these concerns and ambitions have created the idiosyncratic curricular structures and characteristics that were different in various places and that created different research traditions, which therefore developed theories of the first level of abstraction (service-providers for efficiency) that became criticized by theories of the second level of abstraction (the “reconceptualist movement,” which blamed the theories of the first level of abstraction for being conservatively bourgeois). This reconstruction itself represents the third level of abstraction and is, in fact, as far as we can see

today, the key to understanding internationally institutionalized educational practices. Engaging in this kind of curriculum theory certainly does not imply any aims at advising curriculum-makers but pursues, in principle, more epistemological than practical goals. It can be labeled “practical” in that sense as it provides a broad, historically-informed international-comparative repertoire of ideas that may indeed be intellectually helpful for those engaged with the second level of abstraction who are struggling for ethically “better” standards in curricula as instruments in the making of loyal national citizens. Needless to say, however, this kind of theory does not meet the ideal of theory as objective in the classical sense, but it at least appropriately faces the plurality of curricula. In any case, one cannot expect more from a theory devoted to the practices of human action.

Introduction

One of the major concerns in the field of curriculum theory (CT) today has to do with the theoretical understanding of curriculum change. Who are the actors and forces driving curriculum change? I would argue that in order to understand these issues in a globalized world, we have to have theories and theoretical concepts that enable us to move beyond limited modernist approaches focused on linear processes of implementation. In this article, I will build an analytical argument for the use of new institutionalism, and especially its latest branch, discursive institutionalism (DI), as developed by Vivien Schmidt (2008, 2011), as a point of departure for such a dynamic analysis of curriculum change, which has hitherto been used very sparingly within the field of CT (cf. Young, 2015). In building my argument, I take my point of departure from Pinar et al.'s (1995) distinction between curriculum as development and curriculum as understanding. However, instead of treating them as historically exclusive, I see them as complementary. Curriculum as development refers to the different ways in which CT contributes to the development of curriculum texts and syllabuses and produces research of relevance to such developmental processes. Curriculum as understanding, in turn, refers to CT—at the same time—being able to make use of a variety of theoretical approaches in critically examining those very developmental processes. Such a critical approach gives the field of CT relative independence with respect to political, economic, or any other interests that are external to education (cf. Uljens and Ylimäki, 2017). Both development and understanding are thus legitimate and necessary approaches to CT. However, when looking at recent developments, there has been a strong move toward curriculum researchers providing useful knowledge to solve problems relating to policy and/or practice in line with curriculum as development. Following Biesta et al. (2019), I would argue that this development has become problematic as it seems to happen at the expense of educational research making use of its critical potential. Against this background, the contribution of new institutionalism to CT, as discussed in this article, should be seen first and foremost as a contribution to strengthen a theoretical understanding of curriculum, although I would argue that critical analysis also contributes to curriculum development.

New institutionalism

New institutionalism emanated during the 1990s out of the work that John W. Meyer and colleagues at Stanford University undertook in the late 1970s and 1980s. In their analyses, educational institutions were treated as loosely coupled systems in which societal legitimacy replaced technical efficiency as the core organizing principle. The basic assumption was that educational institutions did not seem to conform to general principles of organizational theory. Although loosely coupled, educational institutions, at the same time, seemed to be unexpectedly stable over time. This anomaly to organizational theory was explained by their capability of conforming to norms and values and, in doing so, maintaining the trust and legitimacy of the public at large. However, although acknowledging the role of values, norms, and shared beliefs as constitutive for educational institutions, their analyses still took place within a framework where “[E]ducation was seen as being fully controlled by government and the professions and thus beyond the grip of the market forces” (Meyer and Rowan, 2006, p. 3). During the 1990s, such an analytical approach became increasingly problematic as advanced capitalist countries entered into a period of neoliberalism characterized by flexible labor markets, minimized welfare states, and free-market solutions to economic problems, thus reducing the importance of geographical barriers. These were fundamental societal changes that called for new analytical concepts and approaches in order to understand how nations would adopt new ideas and pursue different policies during the process of reorganizing their political-economic activity. The development of new institutionalism can therefore, in many ways, be seen as a theoretical and analytical response to the societal and institutional

changes that were taking place in the wake of the emerging neoliberal paradigm (Campbell and Pedersen, 2001). Eventually, this new institutionalism developed into different traditions, such as historical institutionalism (HI), rational choice institutionalism (RI), sociological institutionalism (SI), and DI. In general terms, HI directed its analytical focus onto historical regularities and the ways in which historical paths continued to shape and guide future action. RI placed its analytical focus on the incentive structures within which rational people make decisions, and SI focused on the cultural norms framing human action. Taken together, these strands of new institutionalism first and foremost contributed to an understanding of the different ways in which institutional rules operate as constraints to human action. They provided explanatory power for issues of institutional continuity and the way in which humans conform to historical and structural rules, rather than for issues concerning institutional change. Following Schmidt (2008), the fourth tradition, referred to as DI, could be seen as a reaction to this lack of analytical interest in why human institutions change. She suggested that in order to understand institutional change in a globalized world, we would have to turn to communicative concepts, such as discourse and ideas, and adopt a more dialectical approach to human institutions as simultaneously “given (the context within which agents think, speak, and act) and as contingent (as the results of agents’ thoughts, words, and actions)” (Schmidt, 2008, p. 314). Understanding institutions as internal to actors thus adds a reflexive element to the institutional analysis, as “people constantly generate representations of what they do as part of what they do” (Chouliarakis and Fairclough, 1999, p. 25f). DI thus places greater emphasis on agency than the other branches of new institutionalism do, which makes it especially suitable for the analysis of curriculum change.

Discursive institutionalism

As is often the case with different branches of theoretical traditions, there are no Chinese walls to separate them from each other; instead, they overlap in many ways, which is also the case with the different branches of new institutionalism. Therefore, DI should be seen as complementary rather than as exclusive to the other traditions, distinguishing itself by paying greater analytical attention to the role of discourse and ideas. In taking on a communicative approach, DI enables a more dynamic analysis of institutional change. While the other traditions adopt a rather one-directional analytical approach “by positioning institutions as in stable equilibria” (Schmidt, 2011, p. 107), DI takes on a more multidirectional approach following a communicative rationale.

Discursive institutionalism by contrast, takes a more dynamic view of change (and continuity) by concentrating on the substantive ideas developed and conveyed by “sentient” agents in discursive interactions that inform their policy-oriented actions which in turn serve to alter (or maintain) institutions. Schmidt (2011, p. 107).

In acknowledging the possibility of agency as a force that not only maintains but also alters institutions, DI adds explanatory power to the analysis of institutional change. In the following, I will discuss ideas and discourse as central DI concepts enabling a more dynamic and multidirectional approach to institutional analysis.

DI distinguishes between three kinds of ideas: policy ideas, programmatic ideas, and philosophical ideas. Policy ideas are the most rapid form of ideas whereby these new ideas turn up in times of an event or crisis and open up a window of opportunity (Kingdon, 1984). However, as pointed out by Schmidt (2011), this should not be misinterpreted as if it is only when a window of opportunity opens up, triggered by an external event or crisis, that new ideas drive policy change. Policy ideas themselves can also contribute internally to institutional change by building up reform pressure that might open up such a window of opportunity. Such a multidirectional approach suggests that processes of institutional change are more complex than what can be captured in simple formulas of stimuli and response. It also shows that there are no watertight barriers between the communication taking place inside and outside of human institutions; instead, they are intertwined, influencing each other in both directions. In turn, rapidly changing policy ideas are often constitutive elements of more general sets of programmatic ideas. These programmatic ideas change more slowly as they are built into the life and structure of institutions where they function as frames of reference. Although some frames of reference prevail as dominant over time, it can also be the case that different frames of reference at any given time struggle for dominance (cf. Young, 1971). Therefore, frames of reference are here understood not so much as homogeneous sets of ideational elements, but rather as a result of discursive struggles. Finally, philosophical ideas refer to a deeper and longer-lasting form of ideas. These are confined largely to the political and public spheres, operating as broad concepts tied to moral principles and values. Such ideas are manifested in ideologies, public philosophies, and world views, and thus they change very slowly.

Turning to the concept of discourse, DI distinguishes between two types of discursive interaction: coordinative discourse and communicative discourse. The two types of discursive interaction relate to what could be understood as different spheres of communication. Coordinative discourse refers to the policy sphere, involving actors such as policymakers, politicians, government officials, experts, lobbyists, union leaders, and so on, operating in transnational, national, and/or local policy arenas. The discursive interaction taking place in this sphere of communication strives toward cognitive justification among policy actors in different kinds of discourse coalitions. Communicative discourse is directed toward the public sphere and involves actors such as the media, interest groups, social movements, and the everyday talk of people in digital fora as well as in real life. Here, the cognitive ideas deliberated over by policy elites during coordinative discourse are communicated to the public in an attempt to gain normative justification. In the context of DI, a focus on discursive interaction directs attention to the importance of the actors involved, as discourses never

float freely; they are acted out by thinking and speaking agents who communicate their ideas through deliberation and contestation, leading to collective action (Schmidt, 2011). This is important as it makes a difference who speaks to whom about what, where it is done, and for what purpose.

Taking on such a differentiated approach to ideas in understanding discursive interaction as a multidirectional process thus facilitates a more dynamic analysis of institutional change than the other branches of new institutionalism do. The different forms of ideas lend explanatory power to a more profound analysis of both institutional change and continuity. In turn, the division of discursive interaction into coordinative and communicative discourses enables a balanced approach to the analysis of institutional change, taking both structure and agency into account.

Curriculum as a discursive practice

From having had quite a functionalistic approach to the curriculum as something to be developed in an almost technical manner, during the 1970s, CT started to take a greater interest in the curriculum as a societal phenomenon (Pinar et al., 1995). Here, Michael Young's edited book *Knowledge and Control*, published in 1971, was an important contribution to the establishment of a new interpretative paradigm (Torres and Antikainen, 2003). The analytical focus was now directed toward the selection and organization of official knowledge and issues of power and control. CT adopted a more societal approach, trying to understand the role of schools and educational systems in the cultural reproduction of societies. The field of CT no longer regarded "the problems of curriculum and teaching as 'technical' problems, that is, problems of 'how to.' The contemporary field regards the problems of curriculum and teaching as 'why' problems" (Pinar et al., 1995, p. 8). Asking why questions then opened up a more complex understanding of the curriculum as a social practice involving many different actors acting out of different interests and with different resources at their disposal. At the same time, the critical question of why implied that things could be different. The task for CT was therefore not only to provide a better understanding of the current curriculum, but also to discuss what alternatives might be at hand.

Conceptualizing the curriculum as an interactive practice among different stakeholders and interests also led to the adoption of an interactionist approach to the central question of CT: What counts as knowledge? The idea of representational knowledge had to give way to philosophical and sociological approaches emphasizing the social construction of answers to questions of what counted as knowledge. Central here was the idea that all knowledge is related to social interests. In addition, theorists such as Richard Rorty, Jürgen Habermas, John Austin, and John Searle, among others, contributed widely to the understanding of such processes of social construction as fundamentally communicative or discursive in character. One could say that they understood the relationship between language and the world as internal, where language was no longer seen as just a representation of the world, but also as part of it and its continuous reconstruction. As pointed out in this tradition, we do things when we speak to each other, conceptualizing language as a social practice among other social practices (Chouliaraki and Fairclough, 1999). Such an approach directs attention to curriculum as a discursive practice. That what is referred to as the official knowledge of a national or local curriculum is the result of discursive interaction among different stakeholders representing different social interests. And that the official curriculum continues to communicate and challenge as it is being recontextualized into different social settings, while other simultaneously deliberate and plan for new curriculum reforms. Answers to questions of what counts as knowledge are thus never static, but continuously constructed and reconstructed in discursive interaction among a diversity of stakeholders within and between different geographical spaces.

Drawing on the work of Habermas, Fritzell (1996) suggests that formal education as a discursive practice at its most fundamental level can be understood following two rationales. One is a communicative rationale that refers to educational actors' intersubjective construction of meaning, and the other is a system rationale that has to do with issues of governability and strategic decision-making. Although touched upon very briefly here, this division helps us to identify formal education as a teleological practice guided by different rationalities and interests, where some can be said to be of more interest to education than others. Here, Pinar (2019, p. 108) points out that:

[T]he educational point of the public school curriculum is understanding, understanding the relations among academic knowledge, the state of society, processes of self-formation, and the character of the historical moment in which we live, in which others have lived, and in which our descendants may live.

From a curricular point of view, this discursive construction of understanding should not be mistaken for conforming to a pre-determined end, but rather it should be seen as an invitation to engage in curriculum as a complicated conversation between diverse actors (and interests) (Pinar, 2019). In making use of such a discursive conception of the curriculum, the role of CT can never only be about providing easy answers so as to develop policy and practice along a system rationale. Instead, by following a communicative rationale, it also has to include a critical component aiming at provoking educational actors at all levels to critically reflect upon themselves, their practices, and the world (cf. Pinar, 2019). As such, CT can be described as a critical science of change, as "critique is central to the issues of freedom and change" (Popkewitz, 2020, p. 222). Thus, this is not merely a critique for its own sake, but a productive one, provoking people to engage in discursive interaction on curricular issues.

Curriculum as an increasingly complicated discourse

The complicated curriculum discourse has traditionally been conceived as a practice taking place within national borders among a variety of educational actors, such as teachers, students, local school authorities, politicians, policymakers, unions, media, academics, and the public. Through the communicative interaction among this multitude of actors, collective national narratives are developed, expressing national values, shared myths, and symbols, placing people in a collective whole, where the authoritative curriculum-as-document is understood as an interim resolution to such a continuous, ongoing national discourse (Westbury, 2008). Irrespective of the construction of such narratives, the curriculum is, by definition, a selective practice where educational actors struggle for interpretive precedence. It is not only a question of what should count as knowledge, but is also always a question of “Whose knowledge should be taught, by whom, and in what ways?” (Apple, 2008, p. 40). Furthermore, this is not only a question that is discussed by a multitude of actors, as these actors also operate at different levels of curriculum making (Deng and Luke, 2008). Deng and Luke distinguish between three curriculum levels: the institutional/societal level, the programmatic level, and the classroom level. The institutional/societal level refers to the overall educational ideas of a specific society and their public legitimation. The programmatic level, in turn, has to do with the way(s) in which values and content knowledge are organized in curriculum texts and syllabuses. Finally, the classroom level refers to students’ and teachers’ experience of the curriculum as it is acted out in the classroom. Such a multilevel approach contributes considerably to the understanding of the curriculum as a complicated discourse connecting different actors at different levels of curriculum making. However, due to the emergence of new transnational policy spaces influenced by powerful organizations, such as the Association for the Evaluation of Educational Achievements (IEA), the Organization for Economic Co-operation and Development (OECD), the United Nations Educational, Scientific and Cultural Organization (UNESCO), the World Bank, and so on, the nation state has become destabilized as the natural site and scale of educational politics (Lingard and Ozga, 2007). The curriculum discourse has thus become even more complicated, as it is now increasingly intertwined with conversations taking place in the transnational arena, thus challenging the field of CT to make use of theoretical perspectives and concepts by widening its analytical gaze to also include a transnational dimension (Nordin and Sundberg, 2018; Wahlström and Sundberg, 2017).

The argument made in this article is that new institutionalism could contribute to such a multilayered and multidirectional understanding of the curriculum by acknowledging the transnational dimension. Especially DI offers a theoretical language capable of discussing both institutional continuity and change in a complex global context. As pointed out by Uljens and Ylimäki (2015, p. 39), “Discourse-oriented curriculum theory provides a language for talking about the human interaction and interpersonal dimensions of any level, from classroom to transnational.” In the following section, I will bring CT and DI together to further explicate my argument for the relevance of DI to CT in order to better understand this multilayered discursive interaction in a global context.

The contribution of discursive institutionalism to curriculum theory

By understanding the curriculum as a discursive practice taking place in a global context, DI has a lot to offer to CT. In this section, I will point to some of its central contributions. First, I will say something about DI offering a language through which to connect the different analytical levels of CT from the local to the transnational. I will then continue by saying something about the ways in which DI lends explanatory power to issues of curriculum change and continuity, and finally, I will discuss the critical potential of agency.

A language to connect the analytical levels of curriculum theory

The emergence of new transnational policy spaces that revolve around powerful actors, such as the IEA, the OECD, UNESCO, the World Bank, and others, has been revolutionary to education, both in terms of governance and to the way in which education has been incorporated as a natural part of a neoliberal policy discourse. In the last few decades, these transnational policy fields have increasingly come to center around the production and use of numerical data gathered through the use of international large-scale assessments (ILSAs), such as the OECD’s Program for International Student Assessment (PISA), and the IEA’s Trends in International Mathematics and Science Study (TIMSS) and Progress in International Reading Literacy Study (PIRLS), and many more. Although they are not part of the formal governing structure for national educational systems, these transnational spaces operate as systemless systems (Lawn, 2013) exercising soft power; that is, as an indirect form of governing exercised through competition visualized in league tables and ranking lists, building up pressure for states and regions to act. These policy spaces are by no means value-neutral; they harbor ideas about what norms, values, and knowledge are of most worth. Since they have been built up around the production and use of educational statistics, objective and decontextualized knowledge have become imperative here. The knowledge produced in the educational system is only seen as useful if proven objective. Although this is not talked about as an educational ideal, that is what it has become, as educational systems have started to adjust to the political quest for objective knowledge at all curriculum levels (cf. Nordin, 2018). Among world-culture theorists coming from the tradition of new institutionalism, these processes have been discussed in terms of an increased world-culture of schooling, as national school systems conform to discourses dominating the transnational policy space (cf. Meyer and Ramirez, 2012). In so doing, world-culture theory has provided important insights into the ways in which national school systems conform to external pressure. However, at the same time, the approach has received criticism for not

paying enough attention to the influence of national and local contexts in processes of translation and transformation as global ideas are recontextualized within national borders (cf. [Nordin and Sundberg, 2014](#)). However, I would argue that adopting a discursive approach provides a theoretical language enabling CT to overcome such contrapositions connecting the different levels and facilitating a better understanding of processes of change as ideas are reinterpreted and translated when traveling within and/or between different curriculum levels. Furthermore, what new institutionalism has shown is that such processes can no longer be understood solely as processes taking place within national contexts. Therefore, adding a transnational dimension to the analysis of curriculum change seems vital in order to be able to critically examine the reconfiguration of national educational systems today (cf. [Autio, 2009](#); [Uljen, 2018](#)). Here, new institutionalism offers a fruitful approach to the different ways in which transnational policy spaces and their powerful actors today operate as part of national educational institutions, governing at a distance through soft power.

Analytical concepts to understand curriculum change (and continuity)

DI contributes to a nuanced understanding of curriculum change and continuity as a multidirectional process in adopting a stratified approach to the concept of ideas. First, in conceptualizing ideas as the substantive content of discourse, DI acknowledges that educational discussions on knowledge always mean talking about something, which, irrespective of interpretation, cannot be reduced simply to discourse. Questions of how are always related to questions of what. However, having said that, it is also true that ideas never float freely; they are carried by thinking and speaking actors operating out of different interests and with different resources at their disposal. Answers to the question of what counts as official knowledge are therefore never given in advance; instead, curriculum actors are involved in a continuous struggle for discursive dominance. The lesson to be learned from new institutionalism is that issues of what counts as knowledge in a society, and in schools, are discursive in character. Using a stratified concept of ideas enables curriculum analyses of such discourses by acknowledging aspects of both time and space. By using such a stratified approach to ideas, DI contributes to a context-sensitive analysis of curriculum change and continuity by showing that when decontextualized transnational discourses are recontextualized within geographical borders, they are confronted with a variety of institutional ideas, of which some can easily be changed, while others are more resilient, depending on the contextual conditions and to what extent they are part of more deeply rooted philosophical ideas. Such a stratified approach to the discursive interaction of ideas thus facilitates a multidirectional analysis of what happens when ideas travel within and/or between different curriculum levels, and why some ideas change in the complicated discourse of the curriculum while others do not.

Curriculum actors as agents of change

DI criticizes the other traditions of new institutionalism for not paying enough attention to agency. Although, from slightly different positions, they all treat human institutions as relatively stable rule-following structures external to human actors. As such, institutional rules serve mainly as constraints for human thinking and action. In adopting a dialectical approach, DI instead sees human institutions as “internal to the actors serving both as structures that constrain actors and as constructs created and changed by those actors” ([Schmidt, 2008](#), p. 14). Institutions are thus understood as reflexive discursive practices, placing greater emphasis on agency, as people, through their discursive actions, are acknowledged as capable of not just maintaining but also of altering the very institutions of which they themselves are part. From such a point of departure, educational actors at all levels are recognized as agents of change in the complicated curriculum discourse. Of course, some actors do become more influential than others due to differences regarding resources, but from a theoretical point of view, it is important that all actors who are involved are recognized as possible agents of change, since windows of opportunity not only open up as a response to external stimuli, but because the actors themselves can build up pressure to open up such windows, making change possible. A focus on agency thus carries a critical component into the analyses by acknowledging that things could be different. As pointed out by [Popkewitz \(2020, p. 222\)](#), “[C]ritique is an optimism about the possibilities of change.” Such a critical approach to CT means directing why questions to processes of institutional rule-following, examining the norms, values, and ideas guiding such processes, and what actors and interests are involved. The critical potential of CT then lies in its relative independence from any interest external to education, be it political, economic, or other, enabling curriculum researchers to pose critical questions about what is of most worth to education. In making use of its critical potential, curriculum research can then contribute to opening up discourses that are seemingly inescapable and closed in order to facilitate a broader understanding of curriculum change in a globalized context. By insistently asking inconvenient questions of what might be of most worth to education, CT then contributes to curriculum development not just through a provision of solutions to practical problems, but also through provocation, challenging educational actors to make use of their critical potential.

Concluding remarks

In this article, I have argued for the usefulness of DI to CT and to the study of curriculum change. Adopting a DI approach enables the dynamic and multidirectional analyses of the curriculum as a complicated discursive practice. DI also provides a theoretical language for connecting different curriculum levels and for analyzing processes of change as ideas travel within and/or between

them. In understanding institutions as internal to humans, DI positions educational actors at all curriculum levels as agents of change. As such, educational actors always hold the potential of both maintaining and altering the very institutions of which they themselves are part.

To finish, I would like to stress that in a time when the functionalist rationale has once again come to dominate curriculum research in many parts of the world, the need for a critically oriented CT has become more important than ever. Without such research, CT runs the risk of getting out of balance if its analytical interest is narrowed down to a matter of finding solutions to practical problems formulated by educational policy and/or practice. In order to maintain a theoretical balance between curriculum as development and curriculum as understanding, CT also has to conduct critical research, asking inconvenient questions, and provoking actors at all curriculum levels to think differently about the educational institutions of which they are part. What I have tried to do in this article is to argue for the usefulness of DI in such critical and reflexive analyses of curriculum change (and continuity) in today's global educational context.

Introduction

The OECD (Cerna, 2014) has reported that in the early part of the current century there had been large increases in pedagogic practices across all countries in such areas as relating lessons to everyday life, high order cognitive skills, data and text interpretation. Paradoxically, however, there is a long tradition of concluding that schools are very resistant to change. The educational literature is full of accounts of and commentaries on pedagogic and curriculum innovation, large and small, reflecting a lack of change:

It can be said that by and large [schools] have not changed fundamentally over some decades.

Tangerud and Wallin (1986, p. 45, Sweden).

The most remarkable feature of the educational system is its capacity for continuity and stability in the face of efforts at change [We are confounded by] the inability of innovations to transform the schools.

House (1979, pp. 9 ± 10, USA).

When we speak of an innovative school, we mean one that tries one new thing after another without making any of them work.

Runkel (1984, p. 178, USA).

These evaluations might come from thirty plus years ago, but in the late 1990s conclusions had not changed substantially (Cuban, 1998; Spillane, 1999), nor in the new century (Elmore, 2004, Supovitz, 2008). Hallgarten et al. (2015) reach the same conclusion and attribute the atrophy to the constraint of high stakes testing systems. The paradox arises substantially because there is confusion about what constitutes innovation in pedagogy and curriculum. There is no shortage of mandated reform and there are frequent changes in the content of curricula, but the effects are often negligible.

Convergent and divergent pedagogy and curriculum

The main tenet of this chapter is that innovation in pedagogy is best understood through the degree to which the teacher pursues convergent or divergent outcomes. This distinction is well articulated through the work of Torrance and Pryor (1998) in relation to assessment, one of the three message systems of schooling identified by Bernstein (1971), the other two being curriculum and pedagogy. However, it is also reflected in the work of a range of other authors, including Sfard (1998) and Lingard (2005). Torrance & Pryor developed their framework through the observation of primary school classrooms in England focusing on formative

assessment practice. They summarized the two extremes that they encountered in [Table 1](#), while acknowledging that some practice occupied an intermediate position.

A convergent pedagogy proceeds from the intention that the learner will learn or master something that is pre-determined and thus not open to negotiation. This aligns most closely with curriculum as content model ([Kelly, 2009](#)) where the driving purpose is for students to learn and reproduce subject content, which is generally taught in subject specific lessons. The teacher is positioned in authority, assessing the degree to which the specific content has been mastered. There is likely to be frequent teacher talk episodes, many tasks will relate to comprehension, understanding and application of subject content (facts, concepts and ideas) and assessment is geared to checking performance or retention of subject content. It is highly significant that interaction is characterized by the I-R-F sequence ([Sinclair and Coulthard, 1975](#)). In this pattern, the teacher initiates (I), usually with a closed question, a student responds (R) and the teacher provides feedback (F) based on the degree to which the student has matched the expected, “correct” answer. [Sarason \(1990\)](#) summarized a large number of US studies and reported that teachers asked 45–150 questions per 30 min, but students asked less than two in return! The contrasting, divergent assessment and pedagogical style has significantly different characteristics starting from the intention which is to stimulate the development of the young person and assessment aimed at determining what has been learned, whatever that may be. Torrance & Pryor made the point that this mode reflected different understandings of learning and how to use assessment to support it. In this pedagogical mode tasks are more open, but it is in the resultant interaction that more critical differences occur as the teacher is provocative or exploratory in feedback, generating debate and discussion and inching toward reflection and metacognitive insight. Furthermore, the curriculum is to some extent malleable and can be shaped by the students’ response, and thus those students are not subservient to the curriculum. The I-R-F pattern is disrupted and there is space for the student to initiate on the basis of curiosity, which is too often neglected in curriculum formulations. In Torrance & Pryor’s work convergent pedagogy was the norm and evidence generally suggests that it is a universal pattern.

The significance of a divergent curriculum is indicated by the concept of *subjectification* in education ([Biesta, 2012](#)). Subjectification sits alongside qualification and socialization as one of the purposes of education, with qualification representing the process of accrediting the mastering of knowledge, skills and dispositions, and socialization representing the process of becoming a citizen through the adoption of cultures, traditions and acceptable behaviors. Subjectification, however, is the development of the unique individual human, growing into their talents, such as the arts or sports or humor or, indeed, empathy. Biesta attacks the lack of attention given to the purposes of education, and this concern is echoed by many others ([Alexander, 2010](#); [Au, 2012](#)). Furthermore, Biesta draws attention to the centrality of interaction in education as teachers seek to influence their students, but he problematizes this process in that interaction is not simple teaching action and a resultant learning “effect”, it is a “hermeneutic” process, because students interpret the teaching action, whether it is through teacher words or tasks set. There is no perfect match between education “input” and “output” as is sometimes assumed in the widespread use of objective-led teaching geared to high stakes testing. For Biesta education assumes that teachers are aiming to foster independence in adult life, fulfilling their human potential in leading “good” lives, and he pinpoints (p. 585) unpredictability in interaction and interpretation:

If teaching is going to have any impact on students, it is because of the fact that students interpret and make sense of what they are being taught, not because the teaching would simply flow into their minds and bodies. Yet the art of interpretation is a fundamentally open art which lodges an element of unpredictability at the very heart of education.

The threats brought by uncertainty underpin much of the debate and struggle in the domain of pedagogic and curriculum innovation. Increasingly education systems and their manifestation in curriculum crave predictable and controllable outcomes ([Ranson, 2003](#)). This is partly because political systems want schools and teachers to be accountable for the task and monies devolved to them ([Rizvi and Lingard, 2006](#)). More widely such accountability reflects an increasing managerialism in public life, in which numbers govern the conduct of public services through a series of targets and technologies to gather data to monitor those targets. The emergence of this dominant thinking in education reinforces convergent pedagogies, with set objectives and an educational mindset and system that is geared to sticking close to those objectives and banishing uncertainty. Many in public office experience

Table 1 Some characteristics of convergent and divergent assessment based on [Torrance and Pryor \(1998\)](#).

<i>Convergent assessment</i>	<i>Divergent assessment</i>
Assessment which starts from the aim to discover if the learner knows, understands or can do a predetermined thing. Some implications:	Assessment which starts from the aim to discover what the learner knows, understands or can do. Some implications:
a. Precise planning by the teacher focused on objectives;	a. Flexible or complex planning which incorporates alternatives;
b. Closed or pseudo-open teacher questioning;	b. Primarily open tasks with “helping” questions;
c. Feedback focused on performance and the successful completion of the task;	c. Feedback as part of discussion prompting reflection on the task and its context with a view to constructing understanding;
d. An interaction based on an Initiation-response-feedback (IRF) sequence;	d. On-going dialog between and among learners and teachers;
e. Assessment controlled mainly by the teacher.	e. Assessment as a collaboration between and among teachers and students.

this as an oppressive form of surveillance (Ball, 2003) which constrains their professional agency and creates a dissonance between their values and actions, which are often out of kilter (Fuller, 2019). Divergent pedagogy does not readily fit in such regimes.

There are interesting links between convergent and divergent pedagogies and Basil Bernstein's concept of framing which refers to "the degree of control teacher and pupil possess over the selection, organization, pacing and timing of the knowledge transmitted and received in the pedagogical relationship" (1996). Strong framing is found in classrooms where teachers maintain control over decisions made concerning the selection of content, the activities applied to them and the pace of lessons. That control is evident in the classroom, through fact that the teacher asks all the questions of consequence, with scarcely any space for student curiosity and questions. Teachers generally plan lessons to set objectives rather to stimulate debate and thought. Weak framing, however, offers some space for the student to determine subject matter and questions to be pursued and would be associated with inquiry-based approaches. Weak is not a pejorative term and it signals a more equal power relationship between teacher and student. The teacher has to be more contingent, responding to the impulses, questions and motivation of the students. Furthermore, it does not mean that subjects have no place, rather that at times they serve the curriculum and the curiosity of students, with teachers taking responsibility that there is coherent subject progression with no glaring gaps.

Productive pedagogies

A further valuable reference point in articulating the nature of pedagogic innovation, is provided by the Queensland School Reform Longitudinal Study (QSRLS) (Lingard, 2007). This research project was focused on analyzing and theorizing school pedagogy and tried to square a difficult circle of promoting positive identity construction and the learning of critical subject knowledge as a partial antidote to disadvantage. To put it another way they were trying to calibrate powerful theoretical constructs with powerful classroom practice. This is against a backdrop of increasing government intervention directly or indirectly affecting pedagogy, with the effect of leaching out attention to difference and contemporary global citizenship. Lingard (p. 50) quotes Bourdieu (1990) as follows:

If all pupils were given the technology of intellectual enquiry, and if in general they were given rational ways of working (such as the art of choosing between compulsory tasks and of spreading them over time), then an important way of reducing inequalities based on cultural inheritance would have been achieved.

The QSRLS finessed the argument that pedagogic and curriculum innovation are critical in achieving social justice outcomes. Consequently, drawing upon work on authentic instruction (Newmann et al., 1995) and wider literature QSRLS developed four dimensions of pedagogies of difference, with sub-categories, for use in classroom observation (Table 2).

What might divergent pedagogy look like?

Three examples, at contrasting scales, are given in this section of pedagogic innovation – Philosophy for (or with) Children (P4C), adopted across numerous jurisdictions, the Integrated Programme (IP) in Singapore, a nation state, and an informal and local network of geography teachers (Thinking Through Geography) in England collaborating around developing metacognitive practice. Whilst the aims and structure of these contrasting

Table 2 Dimensions and sub-categories of productive pedagogies.

<i>Dimensions</i>	<i>Exemplar sub-categories</i>
Intellectual quality	Higher-order thinking; Depth of knowledge; Substantive conversation; Meta-language
Connectedness	Connectedness to the world beyond the classroom Knowledge integration
Supportiveness	Social support Academic engagement Student self-regulation
Working with and valuing difference:	Cultural knowledge Active citizenship Group identities in learning communities Representation

innovations do reflect divergent pedagogy generally, it is important to note that in some contexts they may be distorted to more convergent formats and it is important to remember that high stakes, intrusive testing regimes can thin out pedagogies.

Philosophy for children

P4C is a program originally developed in the US by philosopher Matthew Lipman (Lipman et al., 1980) who was disconcerted by the evidence about the poor cognitive abilities of students leaving high school and entering college. P4C in some form is now used in over 60 countries. Teachers provide a stimulus for school students to excite their curiosity. The students are asked to voice questions prompted by the story or stimulus (which might be a photograph, recording or artifact). Through democratic processes a question is chosen for the class to pursue using protocols to promote listening and the principles of dialog. Haynes and Murris (2011) argue that there is an epistemological shift in the role of the teacher and a fundamental reframing of relationship between teacher and student. P4C does not induce an overnight transformation, as for both teachers and students there can be considerable period of adapting to new divergent norms. The Education Endowment Fund in England has funded a quasi-experimental study into the effects of P4C on maths and reading attainment in primary schools with pupils aged 8–10 years old, involving nearly 50 schools (Gorard et al., 2015). The results indicate a 2 month gain in English and mathematics test scores. Qualitative evidence from both teachers and pupils indicated that P4C had had a positive impact on pupils' confidence to speak, listening skills and self-esteem and thus they were more likely to initiate through their own questions. This evidence along with a number of other studies (Trickey and Topping, 2004) confirms the potency of P4C in breaking open the restraints of the routine talk pattern of I-R-F, in which teachers control talk, ask nearly all the questions in pursuit of right answers converging on the planned curriculum outcomes.

Singapore's Integrated Programme

While P4C is international in its status, the Integrated Programme (IP) is country specific, originating in Singapore and targeted at the top 10% of academic achievers. According to Koh et al. (2014) IP had radical intentions, with explicit mention of diverse experience. They also note that the IP represents a shift in the education system toward a student-centric phase (from 2011), having passed successively through survival-driven, efficiency-driven and ability-driven eras. The student-centric system pays greater attention to social-constructivist understandings of learning in which individual meaning making and creativity are valued. Introduced in 2004, the IP was a government initiative for higher attainers to experience an enriched curriculum surpassing a subject based approach to encourage critical, creative and reflective thinking as well as "leadership, teamwork and communication skills" (Ministry of Education, 2002). While the majority of the school population take "O" (ordinary) Level examinations at age 16, the IP students bypass this certification stage and only take the traditional "A" (advanced) Level qualification at age 18, thus freeing them from the restraints of more convergent "O" Level courses. The school based curriculum planners have had to work hard to adjust school structures to accommodate the IP modules alongside the traditional "O" Levels introducing foundation modules (Level 1), interest-driven modules reflecting staff specialties (Level 2) and modules for developing independent/inquiry learning (Level 3). It is highly relevant that the curriculum planners focus strongly on key concepts in structuring learning rather than more traditional content organization. There is a clear expectation of reshaping classroom practices.

Some teachers are teaching both the traditional "O" level focused course and the IP modules and they are clear about the difference in pedagogy, as reported in Koh et al. (p. 856):

The OP is very simple. You just teach, exam, any time of the day, they just go, no problem. The IP one, you must moderate a bit and put in more activity, so you make things a bit more fluid, a bit more interactive for them. (Teacher D)

Because after a while I realized, OK if I use this method, the IP students get a bit bored, but the OP are OK. If I use another method, the OP students don't get it and the IP students find it exciting. So after a while ... I started to vary the way I teach both classes. For IP, I really try and do more facilitation. That means I give them work, they do it, they present and then as a class, we critic and [it is] more self-directed. Whereas for the OP... I monitor them a bit more closely. So if I notice that they do not understand the particular concept, that's when I have to explain it." (Teacher E)

The IP is perhaps not an outright divergent pedagogy but these comments subtly demarcate the different teaching constructs that are being applied by teachers between the two student cohorts, with interactivity, facilitation, critique and responsibility being offered to the IP students. It is pertinent to reflect that it is only the brightest students that are being offered such opportunities with the sense that they are an elite who need a more expansive education for the long-term health of the Singaporean economy.

Thinking through geography

The divergent practice described by Leat and Lin (2003) focuses on an informal network of Geography teachers developing meta-cognitive outcomes for students and illustrates how teachers can create spaces (see below) for more innovative practice within the confines of a more convergent system. The development of metacognition is a critical element of divergent practice and this

emphasis relies on reflective discussion of thinking. It is interesting to note that the lessons were not part of a program or intervention. Through video analysis and student interviews Leat & Lin identified some key aspects of divergent practice. These included:

- Teachers giving care and attention to individuals and groups to the effect that they feel that their ideas are respected and a focus of interest of the teacher;
- Teachers encouraging students to ask questions;
- A strong press from the teachers for students to expand, explain or justify their answers, thus moving away from the IRF pattern as the teachers do not provide immediate feedback but, as in the Torrance and Pryor study, they provoke and stimulate;
- Perhaps more tellingly the teachers promoting and managing discussion

Overall, there was an emphasis on shared thinking, open discussion and making connections, with an explicit message to students that they are not just learning subject matter but that they are also developing their critical faculties and more complex identities. Furthermore, they are not being treated as a collection of individuals but as a learning collective. The students' interviews provide some insights into their unfolding conceptualizations of learning and learning environments stimulated by divergent dimensions to learning:

Female pupil: She was making us look at other peoples' work to understand, to see what they were writing about.

Female pupil: It's better to have someone else's opinion.

Teacher: Why? I don't think that you are wrong. I want to know why?

Female pupil: Because you can put your ideas and their ideas together and make it like better.

Teacher: Why is it important to talk about your ideas? If you and I sat down now and talked about our opinions or some of our ideas, why is that better than you deciding on your own?

Female pupil: You can find out better ideas than you had and make them better ... And make them more exciting and more serious.

There is no sense here of getting students to zero in on the right answer as quickly as possible, but instead that discussion is a place to share one's thoughts, listen to others, compare ideas, build understanding and be critical. Taken together and in their different ways, these three examples demonstrate an evident concern for developing outcomes that go far beyond the mastering and retention of subject content for examination purposes.

Changing the learner

Divergent pedagogy, as indicated by [Torrance and Pryor \(1998\)](#), has many dimensions that are different from convergent pedagogy, related to teacher constructs and classroom processes but there is every reason to believe that the effect on learners is different. This can be understood in a number of ways that are complementary to one another, as the psychological impact may differ from student to student. However, the central argument is that in divergent pedagogy the learner is interacting with their environment in more complex ways than being taught to master and remember tenets of subject disciplines. A first consideration is that divergent pedagogy is likely to be more "active", not necessarily in terms of making things or concrete actions, but active in the sense that the student initiates and is invited to think and respond. Indeed, in some divergent contexts such as project based, or inquiry-based learning there is explicit scope for action. Dewey's Transactional Theory of Knowing ([Biesta, 2014](#)) suggests that action is critical because it represents the learner acting in their environment, opening up the possibilities of what effect that action has. This is significant because the environment, whether human or natural, will respond to that action, creating some form of feedback, through which one can learn about the results of one's actions. This might be as varied as building something which does or does not fulfill one's goals or engaging in a discussion about an ethical issue that needs tackling. The experience of the action and the feedback constitutes learning from experience. Convergent pedagogy, because it is focused on a reproducing a right response or answer, cannot offer this mode of opportunity to learn. The importance of metacognition comes to the fore in action-oriented divergent pedagogies in that possible actions can be rehearsed in advance and their possible efficacy and consequences evaluated. [Dewey \(1922, p. 132\)](#) terms this intelligent action which he defines as "dramatic rehearsal (in imagination) of various competing possible lines of action". In the classroom environments described by Leat & Lin students are strongly encouraged to rehearse possible lines of action, including thought. Additionally, metacognitive reflection, after the event, permits not only recognition of missteps but also how the experience relates to wider patterns and concepts in subject disciplines.

For some students the experience of divergent learning is transformative ([Mezirow, 1991](#)). The learning experience changes the way the individual sees the world, they have new perspectives on their world and their place in it. It is, to a degree, a whole person change, involving knowledge, values and attitudes, feelings and behavior ([Illeris, 2014](#)). This change can be sudden or incremental ([Cranton, 2002](#)) but involves the individual coming to understand that their view of the world is skewed or limited, and as their perspective changes their assumptions and meaning making processes change. Divergent learning experiences stimulated by pedagogic innovation can have such effects of this magnitude on young people, particularly those who had limited life chances. These two students suggest such an effect after exposure to inquiry-based teaching in their school ([Leat and Reid, 2012, p. 203](#)):

it has made me think about what I can do and want to do when I leave, it has given me more confidence.

I didn't know learning was like this – it's really good because I know what I can do more – to get better at things

In these extracts identity development is evident. In the C21st identity has taken on new significance as the traditional social anchors of religion, class, work, binary gender roles and family have all lost their weight. We have more opportunity and freedoms to author ourselves through work, dress, networks, affiliation, activity and of course social media but it is a bewildering choice with an expectation that we can be anything we choose and that we will be a "somebody".

As Illeris observes (2014, p. 579):

For the generations which grew up during the 1980s and later, the task or duty of creating their own identities became more and more central. Who am I? Who do I want to be? How can I fulfil my dreams? For some, usually those with the more advantaged social backgrounds, possibilities might be great and never-ending. But for others the proliferation of choice became a strain, a continuous demonstration of their insufficient individual capacity to make things function and capture the success and happiness which should be the outcomes of all the choices and possibilities.

Divergent pedagogy, in which experience is planned for and valued, positions the student as an active agent in an environment in which they will have an effect and interact with others. At the more active spectrum of divergent pedagogy is inquiry and project-based learning, where, to use Bernstein's term, framing is weak and students can shape the curriculum in important ways. Students can take on meaningful roles in projects, they are not passive and they can be offered the chance to operate in more diverse social and physical environments beyond classrooms. They can go places, meet people and do and make things. The German psychologist Ziehe (2009) refers to this process as "search movements" where ideas, clothes, views and social roles might be tested out for fit. As competence is recognized by others, including teachers and peers, identity is refined and confirmed especially where there is a sense of collaboration or community (Lave and Wenger, 1991). As a consequence, participation through action is pivotal to identity development, but this stands in contrast to so many secondary schools where students play a needlessly passive role and where responsibility is largely confined to handing completed work to teachers.

It is especially important therefore that during formative years when they are soon to be faced by a precarious and challenging future, that young people should have the opportunity to visit a wide range of social environments and to meet as many people as possible. In addition, they should be challenged to work with these people and their peers and in these contexts, because these divergent experiences will provide them with a rich array of raw material with which to construct robust identities. It is also such processes that begin to establish particular competences or habits, such as creativity, criticality and empathy. Competences are more than skills, they are part of who we are and this comes from substantive experiences and challenges, not superficial classroom exercises which demand such a narrow slice of ourselves.

Rolling the stone uphill

If innovation in pedagogy can produce the beneficial outcomes associated with divergent pedagogies, the question arises as to the stubborn resistance to change as outlined at the start of this chapter. Pedagogic innovation can produce a reaction in schools that has similarities to the immune system in a human body responding to infection. The immune system produces antibodies which fight and (usually) overwhelm the infection. A further metaphor, rolling the stone uphill, captures the relentlessly recurring nature of failure of reform is found in Greek mythology. Sisyphus, the first king of Ephyra was punished by Zeus for his deceitfulness and arrogance, by being condemned to pushing a large boulder uphill, only for it to roll down again as he neared the top, with these events repeated eternally. There was no closure and the boulder never reached the summit. The failure in innovative pedagogy is systemic and by way of explanation one can point to some of the factors which operate at the individual teacher level but also some affecting schools as institutions, and indeed national and global discourse.

Barriers for individual teachers

Individual teachers are conditioned by a variety of socializing forces to teach in particular ways (Leat, 1999). Teachers have been students themselves, taught for thousands of hours which provides an apprenticeship of observation (Lortie, 1975) which creates a mental model of teaching. Once in training and induction there is a certain accepted model of teacherly activity relayed by teachers in the work environment and it is hard to step away from those shaping forces. This can be further reinforced by students themselves who have learned a particular role, usually fairly passive and cemented in the IRF questioning pattern. Many of these questions will be closed and pseudo-open questions in which the teachers stays firmly and deliberately in control. Teachers are generally taught to plan using objectives which demands that they predict what students will learn which becomes the bedrock of what and how they will teach and assess. Teachers are not taught or expected to teach in a manner where learning unfolds and students are given responsibility for some of the choices about manner, pace and direction of learning. A teacher experimenting with thinking skills approaches reported in Leat (1999, p. 391) describes the challenge of changing student expectations and roles:

Pupils were slow to get the hang of what was expected of them, and as a result the lesson quickly deteriorated into chaos The main lesson I have learned from my experiences ... is that they are not easy for pupils to do. The activities, although often apparently straightforward, usually require a certain way of thinking and depth of thought which pupils are simply not accustomed to. It is therefore necessary to 'train' children to learn in a different way, to teach them a variety of interchangeable skills, and to be more adaptable in their learning.

Another obstacle to be overcome is giving up classroom routines. Much of the process of learning to teach involves learning to make classrooms predictable as they are potentially chaotic and unruly in that a teacher is attempting to manage the learning of 25 students who have different needs and interests. It takes a big investment from teachers to establish and embed norms and routines for students, such that if the teacher gives particular instructions students will respond in predictable ways. [Brown and McIntyre \(1993\)](#) developed the concept of Normal Desirable States (NDS), which represents the criteria through which a teacher can judge whether a lesson, or part thereof, is proceeding along the expected lines toward the expected conclusions. If a lesson departs from the expected they will intervene to try to get it back to the NDS, which might be seen as a state of equilibrium. Curriculum innovation, not least in the shape of divergent outcomes, upsets the NDS and teachers and students have to learn a new normal.

School level barriers

Commonly schools do not make it easy for teachers to innovate toward more divergent pedagogies. [Payton and Williamson \(2008\)](#) summarizing the challenges faced by teachers trying to introduce *Enquiring Minds* (an enquiry model) in England detailed a range of very practical obstacles such as timetabling, resources and the dominance of subject teaching:

In none of the schools was there a concerted effort to ensure that the skills and aptitudes of enquiry-based learning, information management and so on were embedded across the routines of the school. While certain teachers did report that they had imported aspects of these initiatives into their subject teaching, these were individual examples and not endorsed systematically across any one participating institution.

In Spain, [Pozuelos et al. \(2010\)](#) in a study of the implementation of an enquiry curriculum project *Exploring Our World* (age 6–12) drew attention to very similar practical problems, but also to teachers' transactional conceptions of teaching. One of the interviewees provides a very trenchant analysis (p. 138):

Enquiry-based learning runs up against the whole fixed and immovable school machinery.

If curriculum innovation requires innovative schools then long-term prospects of change may be limited. [Giles and Hargreaves \(2006\)](#) identify three factors which undermine sustainability of such schools. The first is the additional funds that they may receive in start-up or conversion and their ability to attract key staff, which are rarely continued ad infinitum. The second factor is an alleged life span of innovative schools of creativity and experimentation, overreaching and entropy before they expire or lapse into a survival mode ([Fink, 2000](#)). Thirdly more innovative schools can be overtaken by national policies such as increasing centralized state control. Giles & Hargreaves note a tendency in some jurisdictions for large scale reform with a strong core of standardized testing and accountability to dislodge local innovation. There is a strong conservative default mode in the grammar of schooling, underpinned by governments aligning themselves to the global reform movement.

This chapter does not offer a particularly uplifting perspective, as pedagogy and curriculum remain fossilized in a traditional subject and teacher dominated pattern. Despite the recurring efforts of teachers, researchers and activists to reform there is a Groundhog Day quality to those efforts (Groundhog Day is a 1993 film in which a TV reporter becomes trapped in a time loop, forced to repeat the unsatisfactory events of the same day, February 2nd, over and over). This is no historical accident, although history plays a part. Rather it reflects the decisions that are made by those with political power, who either wish to maintain the status quo or who balk at the challenge of the scale of system change. Furthermore, that conservatism has been bolstered by the new managerial technology of testing and accountability, which believes in the power of markets to improve education, without ever seriously questioning what education might be for.

Discussion

It is instructive to see innovation as a form of social space, following sociological traditions. [Bourdieu \(1996\)](#) was a prime social space theorist through the development of field theory focusing on power for dominance. [Liu \(2021\)](#) argues that social spaces have "natural histories" and exhibit relationships with other social spaces and through this lens of relationships between spaces it is possible to see why pedagogic and curriculum innovation get squeezed. Liu proposes a typology of social spaces: kindred, symbiotic and oppositional. Kindred spaces are essentially similar to each other, while symbiotic spaces are dependent on one another and benefit from exchanges, whereas oppositional spaces are contrasting and potentially hostile to each other. The concept of

oppositional spaces is highly pertinent to innovation in the shadow of mainstream curriculum and pedagogy. For example, [Sannino \(2008\)](#) draws attention to the dominant activity in the context of an Italian school and how it suppresses a promising innovation supported by students from a local university. [Pozuelos et al. \(2010\)](#) and [Stanley et al. \(2012\)](#) provide further evidence that the dominant, convergent pedagogy and curriculum present a threat to innovation, in that the demands it places on educational infrastructure makes precious little allowance for innovation and its different demands. In addition, innovation can be seen as too risky in high stakes environments ([Greany and Waterhouse, 2016](#)). Where there is oppositional pressure there are a number of tactics that can ameliorate the threat such as hybridization of innovation so that it more closely resembles the normative ([Leat et al., 2014](#)), and temporal/spatial solutions whereby the innovation is given some preference at particular times of the year or with particular students (usually low attaining/low motivation).

Liu refers to two important types of actor in these areas of friction between different spaces—guardians and brokers. Guardians, in particular, would have an explicit awareness of the threats to innovation coming from the dominant, convergent school activity and can protect spaces. This is not to argue that convergent teaching is detrimental but that it is only part of a pedagogical repertoire. Guardians can also protect innovation spaces by articulating the benefits of a divergent approach and tracking both its quality of implementation and its impact on students, both areas that are ripe for professional learning focus, through approaches such as lesson study ([Vermunt et al., 2019](#)). It can also be achieved by putting protective borders around spaces where innovation can mature with a view to a longer-term curriculum development. It can be seen as a form of R&D. To feed the innovation process it is advisable to promote the agency of teachers to undertake curriculum development, creating the ecological conditions that support this process ([Priestley et al., 2015](#)).

The significance of the relationship between spaces, one divergent and other more convergent and test related, is signaled by the critique of the social realists ([Young and Muller, 2010](#)), who advocate the place of subjects in the curriculum as a form of cultural capital, without which disadvantaged students are locked out of opportunities for social mobility. While there are well grounded critiques of the approach ([Wrigley, 2017](#)) and a degree of parody in the depiction of more skills-based teaching, there is a point to the argument as exemplified in the QSRLS research, where much teaching even in well-regarded schools lacked intellectual rigor. Young and Muller have characterized three future scenarios for curriculum, Futures 1, 2 and 3, which are respectively traditional subject based curriculum maintaining power and privilege for elites, a progressive (but misguided) challenge to powerful elites with an emphasis on skills, and their preferred but somewhat ill-defined option (Future 3) a symbiosis between Future 1 and 2. They argue strongly for the place of subjects in that they are not arbitrary and represent important knowledge about the world created by communities of scholars over time, not least in mathematics and science, which have hierarchies of core concepts which need to be mastered sequentially.

Part of the value of the concept of Future 3 is the explicit attention given to boundaries. In this “Future” it is the variable relation between the two other “Future”s that is the condition for the creation and acquisition of new knowledge as the respective spaces of Future 1 and 2 become symbiotic spaces in which various forms of boundary crossing and exchange become productive. According to [Akkerman and Bakker \(2011, p. 2\)](#) “A boundary can be seen as a sociocultural difference leading to discontinuity in action or interaction” and the process of surmounting the barriers across spaces is increasingly seen as an important process as the territory is not familiar and there is a vital learning process involved in adapting. For example, [Phelan et al. \(1991\)](#) provide an account of the variable success of adolescents in moving between the world of their peers and that of their families. Thus learning to participate across a spectrum of sites is a measure of success and this applies both to young people ([Akkerman and van Eijck, 2013](#)) and to teachers, if they are to achieve fusion between deep subject knowledge and projects which demand that knowledge and put it to work.

Conclusion

A broadening of pedagogies and curriculum available to students is more likely to come from an acceptance that a range of educational outcomes, such as good subject knowledge, creativity, inclusion and mental and physical well-being, require a spectrum of pedagogies. Such a spectrum may require, among others, for older students something akin to good lecturing from teachers who are masters of explanation ([Wragg and Brown, 1993](#)), creative and performance opportunities and projects which draw on deep subject knowledge and address environmental and social issues in local and global contexts. This needs to be built around a meta-language of learning, shared by teachers and students and promoted by policy. For too long curriculum policy has been lost in an epistemological fog ([Leat et al., 2012](#)), inclined to load its resources into one pedagogical basket believing it to be the “best” or most effective, blind to the fact that the development of the whole person or human capability will need diverse opportunities and experience.

Divergent pedagogy is more likely to be embedded if teachers, schools and curriculum turn outwards and draw together partnerships to support curriculum in its widest sense. There are interesting examples in the US, such as the Community Funds of Knowledge model ([Gonzalez et al., 2005](#)) and the Ohio school improvement model ([Anderson-Butcher et al., 2008](#)). A very good example of what can be achieved comes from Australia ([Tytler et al., 2011](#)) in the Australian School Innovation in Science, Technology and Mathematics (ASISTM) initiative, involving partnerships between schools and community and industry organizations in developing local curriculum projects. These are aimed to overcome the failure of traditional science teaching to reflect the interdisciplinary nature of much science at the frontiers of social, ethical and personal application to real world issues. Projects were co-planned between teachers and associate partners from universities, public agencies or companies, but the best projects were reported to incorporate the perspectives of the partners. Projects were assembled, tested and refined with a changing cast of actors and

with a real purpose, both for improving student experience and providing some service to the community or partners. The authors describe some teachers as wanting to burst the artificial bubble inhabited by teachers and students doing school science and open the school to the community and vice-versa. There is this description of linked projects in one area (p. 25):

BioTech Units at Serendip Sanctuary: The BioTech project in this Geelong satellite area was devised in response to a felt need to strengthen the community engagement of youth in the local schools. The cluster of schools agreed to develop a four-year plan with sustainability as the theme whilst allowing diversity amongst the schools in their curriculum development within this agreed theme. Meg, the coordinator, managed a complex web of initiatives involving visiting scientists and other community members, environmental projects, excursion programs and project-based learning initiatives.

In the description above, Meg, the co-ordinator is acting as a broker across boundaries of different contexts. Subject knowledge is still critical, but the authors comment that ASISTM challenges “the manner and context in which it is developed”. This does imply that there is development needed in teachers’ in pedagogical content knowledge (Shulman, 1987) with a renewed focus on key concepts, if they are to cope with the unpredictability and contingency in pedagogical and curriculum innovation which allows more divergent outcomes.

Such an account places an onus on boundaries and boundary crossing (Akkerman and Bakker, 2011). Teachers need to be able to work with professionals from other settings and accommodate their voices, ideas and perspectives if they are to provide suitable contexts for divergent pedagogy and curriculum. A boundary represents a fault line between one practice or community and another and a divergent curriculum requires teachers who can negotiate those fault lines and draw together people, resources and ideas into a curriculum melting pot. In doing so they are also modeling a vital outcome for students, as increasingly the ability to cross boundaries, thereby displaying some chameleon qualities, is seen as a measure of a successful education for young people (Akkerman and van Eijck, 2013).

Introduction

Teachers' relationship with curriculum is central to the implementation of educational policy and changing classroom practice therefore the words we choose to describe the actions, or the positions teachers take in the curriculum development process matter (Gerrard and Farrell, 2014). Do they execute the curriculum? Do they deliver it? Do they resist it? Do they implement it, or do they enact it? The words we choose matter because they reveal how we construct teachers as professionals and what we perceive, or expect, their role to be concerning curriculum policy directives (Gerrard and Farrell, 2014). They also have an impact on how we support teachers when new curricula, ideas, and practices are introduced.

Curriculum research has long shown that teachers do not passively implement externally determined innovations in curriculum and pedagogy as policymakers intended—they translate, interpret, and mediate them while in some cases they ignore, resist, or dismiss them (Hoyle and Wallace, 2005: 158; Priestley and Philippou, 2018). However, recent discourses and trends influencing global education policy, like for example that of investing schools and teachers with authority for curricular and instructional decisions (OECD, 2020; Priestley et al., 2016), have led to a renewed emphasis on understanding what it means, beyond the rhetorical level, to move the teacher to the center of curriculum decisions at the school level and how the intersection of curriculum and teachers everyday pedagogical and curricular decisions works in practice (Gerrard and Farrell, 2014: 639; Priestley et al., 2016: 188). Within this context, the concept of teacher mediation is assuming a critical role in understanding how teachers make sense of curriculum and negotiate both their positions and the positions of their students within it.

This article reviews the international literature on teacher mediation of curriculum making. We begin by considering how the teacher-curriculum relationship has changed and developed to recognize that teachers actively negotiate their positions in relation to policy directives. We briefly consider key concepts such as "curriculum making" and "teachers as curriculum makers" (these are discussed in greater depth elsewhere in the encyclopedia) before we take a closer look at teacher mediation of curriculum. We then synthesize the literature to provide an account of teacher mediation of curriculum making as a complex and situated agentic experience and practice. The review features studies from different national educational and cultural contexts to illustrate the connections among variables and how global trends create continuities across different policy contexts. We end the article with thoughts on how teacher education and professional development can support both individual and collective teacher sensemaking of curriculum.

From curriculum implementation to curriculum making

For many years the teacher-curriculum encounter (Ben Peretz, 1990) was discussed and researched from perspectives that conceived teachers and curriculum as two separate entities. The dominant image in the curriculum reform literature was that of a passive teacher who receives and implements curricula designed by experts and meant to be followed as "manuals" or "cookbooks" (Craig, 2020: 13). This top-down approach to curriculum aligned with a view of knowledge as "a set of accurate representations of an independent reality" (Rosiek and Clandinin, 2016: 296), a theory that separated the conceptualization and design of curricula from the process of their implementation in classrooms (Giroux, 2011) and models of teaching, embedded, as Parker (1987: 7) puts it, "in the particular value that teachers ought to be competent implementers of others' plans" (see for example behavioristic and cognitive models). As expected, this technical and linear conceptualization of the curriculum development process influenced teacher education and professional development which for several years focused on how to make teachers' behaviors and thinking "more conducive" to implementing externally mandated change (Giroux, 2011; Parker, 1987: 6).

While the phrase "curriculum making" is more than a century old (Catling, 2015: 134), the concept has gained more attention with Clandinin and Connelly's article in the 1992 Handbook of Research on Curriculum (Rosiek and Clandinin, 2016: 299). Based

on their exploration of how teachers find meaning in their teaching experiences, Clandinin and Connelly argued that classroom teachers do not merely implement curriculum as dictated by policymakers but actively experience and make curriculum from their personal and professional knowledge, and they do so every day alongside their students (Ciuffetelli Parker et al., 2011: 4; Craig, 2011: 21). Stated differently, their research indicated that curriculum is made “through the intertwining of the teacher’s life course of action with the students’ life courses of action” (Ciuffetelli Parker et al., 2011: 10) and not through a top-down implementation of policy and prescriptive teacher-proof curricula (Taylor, 2013).

Teacher as curriculum maker—as envisioned by Clandinin and Connelly—is an image that “acknowledges the teacher as a holder, user, and producer of knowledge, a self-directed individual,” an active agent, who negotiates curriculum in relationship with students “unhampered by, though not oblivious to, others’ mandates and desires” (Craig, 2010: 867). Thus, teachers as curriculum makers, in contrast to teachers as curriculum implementers, “not only ... act on their own initiative, [but they are] expected to do so” (Dewey, 1904 in Craig, 2020: 13). That makes curriculum making a deliberative process of interpretation, decision-making, and responsibility and positions both teacher and students as active agents in the negotiation of the curriculum (Deng, 2017; Doyle, 1992: 69; Restad, 2021). As teachers interpret and transform the mandated curriculum into learning experiences, they take into consideration not only their personal and professional knowledge and their students but also the subject matter and the milieu (Schwab, 1983).

Clandinin and Connelly’s work on how teachers’ and students’ lives interact with one another, and curriculum also gave prominence to the term “curriculum of lives”—“curriculum centered in the experiences of many individuals living in relation” (Ciuffetelli Parker et al., 2011: 10). The term captured not only the importance of lived experience but also the relationality of curriculum-making processes. Finally, their work also highlighted the value of studying teachers’ curriculum experiences from a narrative perspective as it allows the unfolding of experience, “as lived,” in the contexts it takes place (Caine et al., 2013). For Connelly and Clandinin (1990), life’s narratives are the context for meaning making of school experiences.

Curriculum making revisited

While the term *curriculum making* is now widely accepted, over the years it has been ascribed different meanings by different authors, many of whom fail to take into account its complexity as a practice (Priestley and Philippou, 2018). As curriculum research continues to explore the “on the ground” (Apple, 2013) realities of schooling and curricula, the development of more holistic and dynamic understandings of curriculum making is important if we want, as Priestley and Philippou (2018: 156–157) argue, to develop “practices that are more sensitive to broader pedagogical purposes and educational principles.”

Approaching school curriculum as “a complex system involving teachers, students, curricular content, social settings, and all manner of impinging matters ranging from the local to the international” (Connelly, 2013: ix), Priestley and Philippou (2018) and Priestley et al. (2021) define curriculum making as a social practice that occurs in a complex web of enactment, as teachers interpret, mediate, translate, negotiate and enact curriculum directives alongside their students and other social actors. The authors use the metaphor of the spider’s web to draw attention to the complexity, the uniqueness and the unpredictability of curriculum making. As a result, it produces unique social practices (Priestley and Philippou, 2018: 154).

A key concept in Priestley et al.’s (2021) approach to curriculum-making as a social practice is that it occurs in multiple “sites of activity.” In contrast with linear and hierarchical conceptions of curriculum making as happening in levels, the idea of “sites of activity,” suggests that curriculum making is made (and re-made) in different contexts, each one with its own kind of engagement and actions in curriculum making (Alvunger et al., 2021: 274). These sites interact and intersect in often unpredictable and context-specific ways (Priestley and Philippou, 2018: 154).

Priestley et al. (2021) identify five sites of activity that are connected in multiple, and non-linear ways, allowing actors to move between sites and influence curriculum making in different ways and multiple directions. These are the supra, the macro, the meso, the micro and the nano “sites of activities,” where activities range from transnational curriculum discourse generation from actors such as the OECD, the World Bank and the European Union (at the Supra layer), to curriculum making in classrooms and other learning spaces as teachers and students interact (at the nano layer).

This systemic way of thinking about curriculum making allows us to understand not only how activity happening in one part of the system influences other parts of it but also that curriculum is always in a state of becoming (Hewitt, 2006: 39; Lingard, 2021: 31): it is constructed and re-constructed as different actors and groups in different sites of activities interpret the curriculum using different discourses to make sense of it (Woods and Wenham, 1995), accommodate its requirements through a variety of mediations (Osborn et al., 2000: 15) and respond to local conditions. A systemic mode of thinking also draws our attention to the fact that as systems change, individuals and groups working within them, also change (Alvunger et al., 2021: 273). That makes Alvunger et al. (2021: 273) argue that “curriculum making is not just a matter of creating the curriculum as product, but a powerful process of learning for those involved as well.”

Compliance, resistance, and creative mediation

The understanding that teachers do not mechanically implement curricula that someone else has written for them and that “any curriculum is a set of meanings yet to be situated and made sensible” by different actors (Olson, 1980 in Parker, 1987) led to a critical question: “How do teachers come between students, curriculum, and milieu, and how does that coming-between, that agency or mediation, shape practice?” (Parker, 1987: 7).

This question has guided a series of studies that took a critical approach to arguments that positioned teachers either as submissive technicians or as contesters of policy and aimed to understand teachers' responses to policy initiatives and directives "as a series of mediations" (Osborn et al., 2000: 12). They did so from the perspective that individuals do not establish a direct relationship with the social-material world (Lantolf and Thorne, 2007). A focus on this direction aimed, according to Parker (1987) to provide

a more accurate and less constraining portrayals of teachers and schooling -more accurate because they do not exclude teachers' tacit and practical knowledge of schooling, and less constraining because they do not presuppose teachers as objects in a curriculum production system (p. 2).

Osborn et al. (2000: 231, 234) conceptualized teacher mediation of curriculum as "the product of successive interpretations and reinterpretations" which are embedded in a dynamic network of personal identity, values, beliefs, understandings, interactions, and structural constraints. In their study of teachers' and pupils' experiences of the 1988 Education Reform Act in England, they identified varied strategic teacher responses to curriculum, which ranged from compliance to imposed changes, through incorporation of imposed changes into existing modes of working, creative mediation, submission to the imposed changes without any fundamental change in values and professional ideology (retreatism) and resistance to the imposed changes. As the same researchers argue, these responses should not be seen "as static or unshifting typologies of teachers":

Rather, they represent role configurations or strategies which individual teachers might adopt and move through at different times and in different ways. Teacher strategies may have varying features at different moments and in response to differing situations. Thus, teachers may sometimes adopt the position of creative mediators and sometimes that of retreatists or resisters (p. 67).

In other words, teachers' mediation of policy and curriculum is not confined to one response or another but moves among strategies (Giroux, 1985; Parker, 1987). The decisions teachers make are more complex than a choice between compliance and resistance as they are based on and are influenced by a variety of variables: personal factors and the social and structural conditions of teachers' work (Coburn, 2005; Maniates, 2010).

Osborn et al.'s (2000) term "creative mediation" has probably been the most influential in the related literature and has been used to capture teachers' creative responses to or creative ways of working within externally imposed guidelines. As Nias (2000: xiv) points out, creative mediators—teachers "who feel able to take active control of educational changes and to respond to them in a creative way" despite difficult and/or uncertain conditions (Osborn et al., 2000: 81)—can be defined as curriculum makers rather than simply policy implementers. Osborn et al. (2000) have also identified four types of teacher response that fall under creative mediation. These are protective mediation, innovative mediation, collaborative mediation, and conspiratorial mediation and all of them indicate that some teachers seek creative ways of working within the mandated curriculum to develop practices in accordance with their values and working situations.

As evident in many studies from different national and educational contexts, curriculum interpretation and mediation by teachers is a continuous process that takes place even under the most prescriptive policies and teacher-proof curricula (Priestley et al., 2021: 6). Teachers function as selective agents (Ben Peretz, 1990: 114) and quickly find ways to mediate the curriculum for their contexts and negotiate their position within it based on their experiences, skepticisms and critiques (Ball et al., 2012: 15; Wallace and Priestley, 2011: 360). From this perspective, they are and will always be curriculum agents and curriculum makers (Alvunger et al., 2021: 284).

How do teachers mediate the curriculum?

When we position the teacher as a mediator and a maker of curriculum—and therefore a person with agency—it becomes clear that teachers' biographies and identities will always be part of what is happening in the classroom (Rosiek and Clandinin, 2016). While for years, several scholars and researchers have been critical of the over-emphasis on the role of the teacher in curriculum-making and the neglect of other important factors, today is widely acknowledged that the individual is still a critical variable in successful curriculum-making, as contextual influences are mediated through teachers' personal resources (Hizli Alkan and Priestley, 2019: 15; Rosiek and Clandinin, 2016; Spillane, 1999).

As mentioned earlier teacher mediation is about how teachers make sense of the curriculum (and their work) and how their understandings and interpretations shape practice. The realization that teachers interpret, mediate and adapt policy, rather than just mechanically implement it, drew researchers' interest in the process of teacher sensemaking and the factors that influence it (Ganon-Shilon and Schechter, 2017; März and Kelchtermans, 2013). A sensemaking perspective allows researchers to understand not only how and why teachers make certain decisions but also why the same policy messages generate such varied interpretations and responses among curriculum agents (Seashore Louis and Robinson, 2012; Wallace and Priestley, 2011: 378).

Sense-making is widely defined as an (inter) active and dynamic process of interpretation and constructing a reality that draws on the sense-maker's pre-existing knowledge, practices, experiences, beliefs, attitudes, emotions, and values (Ganon-Shilon and

Schechter, 2017; Ketelaar et al., 2012; März and Kelchtermans, 2013). As Ketelaar et al. (2012: 274) put it, “sensemaking is more than simply interpreting a message. It is an active cognitive and emotional process in which a person attempts to fit the new information into existing knowledge and beliefs.” For example, teachers’ sense of being powerful or powerless in reform efforts may affect how they respond to them (Wallace and Priestley, 2011).

In the context of curricular decisions and practice, sensemaking is the result of a complex and ongoing interaction between policy content, the relevant prior understandings and experiences of teachers, and the social and structural conditions in which sense-making occurs (Coburn, 2005; Craig, 2020: 125; Wallace and Priestley, 2011: 361). In other words, teachers come to understand policy ideas and curricula by “placing new information into pre-existing cognitive frameworks,” also called “worldviews” or “working knowledge” or “cognitive frames” or “cognitive maps” (Coburn, 2005: 478). As teachers’ personal resources interact with external factors, they mediate, in turn, teachers’ curricular decisions and practices. So, to borrow Spillane’s (1999: 169) argument, by virtue of who they are, teachers can construct very different worlds for learning in their classrooms.

Another influential concept in the literature studying teacher mediation of curriculum making processes is personal practical knowledge (Clandinin, 1985), a term which was coined to indicate that “curriculum is lived and experienced” and to acknowledge teachers “as both knowing and knowledgeable” (Craig and Ross, 2008: 291; Ross and Chan, 2016: 4). Personal practical knowledge is gained through personal and professional experiences and differs from teacher knowledge that is gained from expert sources such as professional documents and support (Clandinin and Connelly, 1996; Ross and Chan, 2016). It is unique to the circumstances and contexts of each teacher as it grows out of their experience and as teachers construct knowledge through their interactions with students, colleagues, parents, and others within and beyond their classroom and school settings (Ross and Chan, 2016: 2). Connelly and Clandinin (1988) understand personal practical knowledge as experiential, emotional, embodied, relational, contextual, and as shaped and reshaped in present situations by past experiences and future plans and actions (Rosiek and Clandinin, 2016: 299; Ross and Chan, 2016: 5). As Ross and Chan note (2016: 5), approaching teacher knowledge from this point of view “enables scholars to consider more carefully the dialectic between each teachers’ personal knowledge and his/her social contexts as knowledge shaped and lived out.” As a result of this “dialectic,” teachers’ personal practical knowledge develops throughout their professional lives (Swart et al., 2018). For Rosiek and Clandinin (2016: 301) personal practical knowledge constitutes “the most important resource in understanding the experienced curricula in classrooms.”

Studying teachers “as biographies with intertwining personal and professional lives” (Kontovourki et al., 2018: 259), research from different social and cultural contexts provides valuable insight into the combination of individual factors that interact to influence teachers’ sense-making and eventually curriculum-making. These include teachers’ histories of where they had taught previously and their memories of past teaching experience (Rosiek and Clandinin, 2016; Willis et al., 2019); previous career experience (Goodson, 2004); teachers’ own experiences as students (from school through university) and the resulting images about what schools should look and feel like (Ross and Chan, 2016); and their socialization as teachers from initial teacher education (Ball, 2014). For example, Kontovourki et al. (2018) in Cyprus, identified a strong interplay between a teacher’s positive previous work experience as “an exemplar classroom teacher” and her identity as a professional who can make curriculum making decisions.

In making sense of curriculum, teachers also draw upon their feelings about their job (Hizli Alkan and Priestley, 2018); the kind of relationship they have with their students and how they conceptualize student needs (Datnow and Castellano, 2000); and their representations of themselves as teachers (Kelchtermans, 2009). Other individual factors that influence how teachers interpret and engage with curriculum are the way they conceptualize curriculum and curriculum making (Hizli Alkan and Priestley, 2018); their dominant mode of reflexivity (Hizli Alkan and Priestley, 2018, 2019); the nature of their connection to policy directives (Kirk and MacDonald, 2001); their sense of familiarity with the changes introduced (Hizli Alkan and Priestley, 2018); their professional knowledge and language (Biesta et al., 2015); teacher subject knowledge and expertise and their subject-based professional identity (Mitchell, 2016). For instance, the less secure teachers feel in their subject knowledge the less capable and willing they feel to engage in curriculum making (Pountney, 2021). Or, as Biesta et al. (2015) found in a study in Scotland, teacher professional language, expressed, for example, in terms such as “bright” or “gifted” children, may guide teacher mediation of curriculum in particular ways.

While teacher individual cognitive processes, biography, and knowledge are important curriculum resources (Rosiek and Clandinin, 2016), sense-making is embedded and situated in social interactions and contexts so from this perspective, teacher sensemaking about curriculum is not solely an individual matter (Coburn, 2005: 478). It is also influenced by the collective sense-making that takes place in formal networks and informal interactions and alliances among teachers (for example the conversations teachers have with their colleagues about policy messages) (Coburn, 2001: 145). In this context, factors such as school culture (März and Kelchtermans, 2013), patterns of social or professional interaction with colleagues (Birbili and Myrovali, 2019; Hizli Alkan, 2020), or conflicting interpretations of policy and curriculum among teachers and school leaders can play a critical role in teacher mediation of curriculum making (Gouëdard et al., 2020).

The increasing policy interest in teachers’ professional communities and interactions (OECD, 2020), as important social sites for meaning making, has led to a growing body of research on the nature, the extent and the dynamics of teachers’ formal and informal connections and networks with the purpose of understanding the role they play or can play in helping teachers to manage the complexity of curriculum making (Coburn, 2001; Hizli Alkan, 2020; Hizli Alkan and Priestley, 2019). For example, how connections or interactions may mediate structural pressures (Coburn, 2001).

Studies also indicate that teacher mediation of curriculum making is integrally bound with the structural, the cultural and the material reality teachers operate in (Alvunger et al., 2021; Hizli Alkan and Priestley, 2018; Maguire et al., 2015; März and

Kelchtermans, 2013). Possible enablers and/or constraints that mediate curriculum-making practices include the size of institutions and subject departments (März and Kelchtermans, 2013); the quantity and the quality of physical resources (Erss et al., 2016); the available support and guidance on curriculum making from authorities, bodies and other actors (Kontovourki et al., 2018); the available curriculum material (Willis et al., 2019); the styles of school management and leadership (Vähäsantanen, 2015); and the “grammar of schooling” (e.g., timetabling, school protocols) (Tyack and Cuban, 1995; Tan, 2016). So, for example, the head teacher’s leadership style and skills may strengthen teachers’ experience in curriculum making and thus work as an enabler (Hizli Alkan and Priestley, 2019: 9). On the other side, a management culture with strong control over teachers’ work and the curriculum may narrow teachers’ agency, as was the case in a Finnish study (Vähäsantanen, 2015). Beyond school settings, the current accountability and examinations systems, the political agendas and even the catchment area of a school (Hizli Alkan and Priestley, 2019: 9), as well as cultural conditions such as parental expectations, school priorities and values and professional learning expectations may also influence how teachers mediate curriculum-making (Willis et al., 2019: 237).

In sum, teachers’ mediation of the official curriculum is a process influenced by a range of different variables at play in any given moment and varies from context to context as factors combine to create conditions of possibility and constraint (Priestley et al., 2012). The connection between these variables and teacher mediation is not a simple causal one—the embedded nature of the various supports and hindrances makes this a complex relationship (Buehl and Beck, 2015; Imants and Van der Wal, 2020; Skott, 2015).

Teachers as mediators of curriculum: the role of teacher education and professional development

In the emerging trend of educational reforms that “ask for teacher agency” and encourage teachers to make personal sense of reforms and enact them at the local level, mediation of curriculum making is perceived as a critical part of teachers’ role in the classroom (Darling-Hammond et al., 2017; Rajala and Kumpulainen, 2017: 312). For example, the idea of actively shaping the curriculum to include all students, their needs and interests, is assumed to be an element of meaningful education (Biesta et al., 2015). This perception has important implications for teacher education and ongoing professional development. Prospective and experienced teachers need the kind of support that would allow them to develop as curriculum thinkers: enriched understandings of the concept of teacher mediation as a process that involves identity, subjectivity, interpretation, and even contestation (Kohler, 2015: 132); the reflexivity to understand their role as mediators, themselves as a resource for mediating and how their own “identities, historicities and subjectivities” (Kohler, 2015: 196) may enhance or inhibit mediation and finally, tools that can help them manage both the mediations that comprise their professional role (Smith, 2017) and other mediators who can make teachers “do things in certain ways” (Alvunger et al., 2017: 3).

In this direction, frameworks and models of professional learning such as professional learning communities, communities of practice, participatory action research and critical collaborative professional inquiry, have become popular, as professional, and social sites which encourage teachers to see themselves as “curriculum agents or inquirers in practice” (Parker, 1987: 7) and engage in “discomforting” dialogs and organized opportunities of collective sense-making (Ganon-Shilon and Schechter, 2017; Kelchtermans, 2009; Molla and Nolan, 2020; Philpott and Oates, 2017; Priestley and Drew, 2017, 2019). Their effectiveness lies, among other things, in honoring the primacy of teachers’ own experiences (Craig, 2011) and acknowledging that individuals will always interpret, mediate, and adapt what is being suggested.

Concluding remarks

As mentioned earlier, by virtue of who they are teachers mediate curriculum making in unique ways (Spillane, 1999). It was also argued that teachers’ beliefs and the actions that result from them are influenced by the social, the structural, the cultural and the material environments in which teachers work. These observations may falsely lead someone to approach teacher mediation of curriculum as a passive reflection of teacher personalities and the environments in which they act (Edwards et al., 2017) rather than the embodied, agentic and dynamic process it is. Osborn et al.’s (2000) “creative mediation,” Priestley et al.’s (2021) definition of curriculum making and even Connelly and Clandinin’s (1988) “curriculum of lives” foreground exactly that: teacher mediation is an agentic, interactional, and adaptive response (Harris, 2013) to mandated curriculum, students and the contexts within teachers and students operate. It is also a process that requires serious commitment to meaningful learning, professional responsibility to pedagogy and accountability to students (Grimmett and Chinnery, 2009). To achieve this kind of agency, teachers need policy contexts and professional environments that create conditions of possibility.

Curriculum development may presuppose a narrow conception of the curriculum as a document or plan, and/or an outdated mechanistic idea of its production. Among the community of curriculum scholars, curriculum “making” has emerged in recent years as a more general and comprehensive term. Despite that, curriculum development seems to be a concept that is still firmly established in the discourse of many educators, among them curriculum developers in public and private organizations. Marsh (2004) noted that the relationship of scholars to curriculum development varies and can be categorized into three groups: prescriptive education-alists have produced models for curriculum development, descriptive researchers study real development practices, and finally, crit-ical theorists emphasize problematic aspects of current approaches to curriculum making.

Terminology

As understood today, the curriculum is a complex social practice that takes place across a number of different but connected places, layers, sites, or even arenas (Priestley and Philippou, 2018). In this text, curriculum development is conceived as a specific part of this broad curriculum-making, more or less confined to a particular level or locus, its desired outcome being some kind of formal curricular document or other resource. The following terms tend to be with a similar or the same meaning: curriculum planning, construction (reconstruction), or curriculum design, with a few more related concepts—primarily “review”—discussed below. The various uses of the term “curriculum design” (or redesign) render the terminology even more complicated. While one might distin-guish between curriculum development as a process and curriculum design as a structure or template of the resulting artifact, some highly competent users also understand by curriculum design a process/practice (e.g., OECD, 2020; International Bureau of Educa-tion, 2021). In such a case, in the design phase the overall architecture/template of the curricular document could be agreed, while the development phase means filling in the template (“design”) with actual subject matter or instructional activities. Such a two-step approach may be almost necessary in vocational education and training, where the challenge is the number of parallel curricula that need to be developed for each qualification.

This text mainly addresses curriculum development at the national (system) level, resulting—if everything goes as expected—in some kind of national or state curricular framework, standards, etc. Thus, we concentrate on macro processes, although sometimes a further distinction is made between the macro-level formulation of curricular policy at the government/nation-state level and the actual development of a curricular framework through the specialized infrastructure at the meso level. The creation of a curricular project in an individual school, often referred to as school-based curriculum development (SBCD), is considered here to be a different process, partly because it is usually more or less constrained by the outcomes of national/state framework development. The previous statement does not imply, however, that curriculum developers at the macro/meso level are unbound. Exactly the opposite, it is undeniable that international actors (supra levels) are increasingly influencing the curriculum development of indi-vidual nations or other jurisdictions, although the assessments of the reasons for these influences and their effects differ somewhat. One of the proofs and simultaneously tools of this influence is the fact that international organizations are key producers and disseminators of guidance on curriculum development and analyses of it (e.g. OECD, 2020).

Historical overview

The English-language literature has usually located the beginning of modern curriculum development into the first quarter of the 20th century. At that time, however, in many countries of Continental and Northern Europe, more or less detailed national or central curricula had been in use for decades. Such documents were construed in parallel with the formation of modern nation-states and were intended to serve them, and it is thus understandable that national governments usually appointed small

committees or commissions that actually wrote the central curricula or syllabi. Such an approach may seem to be undemocratic by today's standards. However, it is possible that—despite flashy and costly public consultations—the current real curriculum development behind the scenes is often still “carried out by a small selection of individuals associated with the Ministry/Department of Education” and individuals with power continue to invite “individuals with educational ideologies (...) attractive to them” to revise the national frameworks (Broom, 2020).

The development of a traditional curricular document (in German: *der Lehrplan*, plan of teaching) has been referred to as *Lehrplanarbeit* (curriculum work) or in similar terms. According to the theory of *Didaktik* (Hopmann, 2015), the basic criterion for the inclusion of a specific subject or content into the plan was to be its value for education (in the sense of “*Bildung*”). In Czech, the term “*warp*” (*osnova*) was used to describe such a document, which is somewhat static in comparison with the English “curriculum”, but promises to capture the essence of the field and at the same time assumes further processing (adding more material) to construct instruction.

Early sorting or tracking of students into different types of schools was common, and the ideas of what was valuable for different groups of students also differed. Thus, the curriculum development for different tracks was guided by different principles. The developers and their contemporaries were well aware, too, that the real process of curriculum development was also a kind of curriculum war (*der Streit/Kampf um den Lehrplan*) of educational powers, i.e., of government, churches, business, society, science and the arts, and tradition. Another form of this battle took place between the subject communities for their discipline's relative prominence and the time allocated to it within the *Lehrplan* (Hericks et al., 2008).

New 20th-century approaches to curriculum development, originating mainly in the United States of America, could be understood as an attempt at a new, more rational approach superior both to the unreflective transmission of a canon of disciplinary knowledge (which was no longer feasible as a result of the rapid development of science) and to partisan efforts to promote the agendas of specific pressure groups. New curriculum construction methods were expected to produce curricula corresponding to the needs of citizens of an industrial democratic society. (And it is precisely the very moment when the revision of the school curriculum was performed from progressive and pragmatic positions, which some authors consider to be the twilight of the great humanistic curricular tradition.) Beginning from John F. Bobbitt in the 1910s, these efforts undeniably culminated in the works of Ralph W. Tyler. According to his famous model (often called the Tyler rationale), curriculum development should proceed linearly by addressing four consecutive issues: (1) What educational purposes should the school seek to attain? (2) How can learning experiences be selected which are likely to be useful in attaining these objectives? (3) How can learning experiences be organized for effective instruction? (4) How can the effectiveness of learning experiences be evaluated (Tyler, 1949)? It can be said that, despite all the later criticism, this “ends-means” or product model of curriculum development still remains attractive to many educationalists and technical-professional knowledge of efficient development procedures is deemed to be crucial for curriculum designers.

It should be recalled here, however, that the Anglo-Saxon countries had a culture of strongly decentralized curriculum development, which was very different from continental Europe. Authors such as Bobbitt and Tyler addressed their recommendations directly to teachers and administrators of individual schools or districts. Their relatively simple technical models still remain very popular in areas such as the development of educational materials or curricula designed for a limited number of users, for example within a single university department. As the procedures for the development of frameworks or standards for entire national systems are being studied today, we understand the necessary knowledge of the developers as less normative, with a greater emphasis on understanding the implementation of the curriculum. The consideration of implementation leads to the fact that today's curriculum theorizing often relies much more on ideas about the role of the teacher and the mechanisms of change in the school as an organization.

Tyler and his successors were interested in curriculum development strategies that produced the necessary curriculum as efficiently as possible. In the family of product-oriented models, goals are set at the beginning and activities are selected according to them. But for a long time there have been different approaches to teaching that did not consider it necessary or appropriate always to start from pre-determined goals and objectives. The proponents of such process-oriented models stressed the value of activities or partial contents from which the teacher can find a way to more general goals. Such models of the planning of learning allow, among other things, greater openness of instruction toward the experiences, interests, voices and needs of students or communities. Education becomes more of an encounter between the teacher and the learner.

Tyler himself later pointed to the importance of three sources of the curriculum, which are the learner, subject matter, and contemporary life. That is how substantive expertise (related to specific disciplines/subjects and to learning processes) and socio-political factors found their way back into his model. This was partly in response to two new trends that influenced curriculum development in the second half of the twentieth century—the cognitive revolution and the reconceptualization of curriculum studies.

In the 1960s, the Cold War and the progress of technology brought a growing demand for new curricula that would facilitate school modernization. New approaches to the selection and sequencing of subject matter were promoted, some based on revolutionary ideas about the child's cognitive development and about the specific characteristics of human learning. The thoughts of Jerome Bruner and Lev Vygotskij had a great influence in this decade. The early encounter of all students with abstract concepts or advanced scientific topics can be an example of the principles used in Cold War curriculum development. In some cases, the resulting documents differed considerably from the previous tradition and their implementation in schools faced serious obstacles and public opposition. The perceived failure of the “curricular reform movement” that was just described had consequences that continue to this day.

Since the late 1960s, however, approaches have been emerging in which the experience gained through the creation of the curriculum and deliberation on it is equally important as, or more so than, the artifact that is produced. This experience of curriculum developers is often self-reflective in its nature. A significant number of educationalists (often called reconceptualists) no longer consider the actual production of the curriculum to be their task at all and instead focus on its analysis and critique, increasingly from postmodern or post-colonial positions, once again emphasizing the political and cultural factors inherent in every curriculum. This turn and growing gap between the language of the people actually responsible for curriculum development on one hand and academics on the other hand could be seen as one reason why in recent decades, theorists have played a lesser role in curriculum development, with other stakeholders such as teachers being given a greater say (Broom, 2016).

The critical attitude of the reconceptualists was further strengthened as curricular policy trends changed in the last decades of the 20th century. Centrally established national curricular frameworks began to appear in countries with a previous tradition of decentralized curriculum making. The two different approaches, Continental and Anglo-Saxon, thus became very close: "Under the perspective of development, curriculum and Lehrplan are exchangeable terms, both focusing on policy processes and state-issued guidelines" (Horlacher, 2018). From an Anglo-American point of view, recent decades of more centralized curriculum development have brought about the decline of teachers' curricular expertise. However, from the point of view of other countries, such as those in Central Europe, teachers have received a highly unusual degree of curricular autonomy.

In the United States, in 1989 the pioneering, albeit controversial, Curriculum and Evaluation Standards for School Mathematics represented an important milestone, being initiated by a professional association of teachers outside official government bodies. This provoked a wave of similar resources for other subjects created by various groups and institutions. Conflict between the global tendency toward comparability of student performance and opposition to a centralized curriculum has been resolved in recent years by presenting the development of a national curriculum as a "bottom-up" project growing from the grassroots or middle level. Since 2010, Common Core State Standards (CCSS) have been developed in this way in the United States as an overarching document. A similar development can be observed in Germany, where after World War II curriculum development was the responsibility of the individual Länder (member states of the Federation), but since 2000, standards have been rising at the national (federal) level (Klieme et al., 2004). In contrast, some traditionally centralized European school systems have introduced two- or three-level curriculum development, which is gradually specified at the national, regional, and school levels. Clearly, this is a permanent search for a balance between central regulation and local freedom and flexibility in curriculum development (Kuiper and Berkvens, 2013).

Curriculum revisions today

The processes described in the previous paragraphs have led to a situation where most nations now have framework curricula or standards, either official or de facto. As a result, macro curriculum development today rarely starts de novo, and in reality we usually encounter curriculum change that has to deal with existing traditions, documents, textbooks, and teaching practices. That is why we now usually come across curriculum revisions, redesigns, renewals, or enhancements. Even curriculum reviews do not limit themselves to analytical/evaluative activities (e.g., the "National Curriculum review for England" announced in 2011 was intended to produce draft Programmes of Study for all subjects). However, the aim of the review need not always be changing the status quo. Arguably, some curricular resources are created with the aim of codifying previous practice, rather than modifying it (Hodge et al., 2019). As noted before, curriculum development could be seen as just one phase in these review/revision processes comprising, e.g., analysis/research, development, implementation, and evaluation, leading to a new cycle again (Curriculum review cycle). However, these processes have been little studied by research and are also undertheorized (van den Akker, 2018; Priestley et al., 2021).

It can be said that these changes have similar goals in all countries—namely to adapt the aims and content of school education to advances in technology and society, or to eliminate existing inequalities in educational outcomes. Sometimes, curriculum revision can only be seen as a periodic housekeeping activity involving minor adjustments, but it is often part of a more ambitious education reform. The OECD (2015) points out to a trade-off between how bold the overall goals of the revision are and how precisely the goals are defined. Some curriculum developers focus on technical issues of the measurability of objectives, often stressing basic skills (and sometimes do achieve improvements in learning outcomes). The second approach, broadly corresponding to the family of processual models defined above, is represented by ambitious reforms setting unconventional goals, but not specific in defining them and often also not successful in achieving them. Today, many education systems are expected to instill key competences/capabilities/21st-century skills. Curriculum development can thus become a genuine search for experiences best suited to the building of capabilities, but also a bureaucratic game aimed at showing the compliance of national agencies with international trends. Multiple goals lead to voluminous curricular documents that tend to be ignored by teachers.

Today's curriculum development—in contrast to traditional models—usually not only builds on the older curricular documents of the given school system (diachronic aspect), but also and especially takes into account the concurrent curricular frameworks of other nations (synchronic comparison). Curricular frameworks subject to revision are often compared against those of nations that

perform well in international large-scale assessments as PISA or TIMSS. Such an exercise may be called international benchmarking (Donnelly, 2005; Oates, 2011, 2017). An example of an approach that simultaneously builds on the continental tradition of Didaktik and contemporary cognitive theory is the method of didactic reconstruction (Duit et al., 2012), combining the clarification of subject-specific knowledge, the analysis of students' understanding, and also the study of teachers' ideas. Another contemporary model that responds to the "back to knowledge" movement was proposed by Rata (2021).

Gradually, both inside and outside the professional community, the awareness has been growing that the actual creation of a document is only one step, and by far not the most complicated one. Thus, during the actual production of the curricular text, the chances of successful implementation or enactment could be increased by an iterative approach to design that includes repeated piloting of draft frameworks in schools. Such an approach is sometimes referred to as design research or design-based research or DBR (McKenney et al., 2006). Another of its key features is the close relation to some theoretical framing that not only guides the development of the curriculum, but is simultaneously elaborated.

Since not only content standards, but also performance standards, have begun to play the role of a curricular document in some countries, psychometric methods, specifically performance standard-setting techniques, have also become one of the curriculum development tools. Last but not least, as national curricular frameworks are no longer (just) glossy brochures and become online platforms supporting planning and teaching in schools, curriculum development also includes designing and coding for the technical aspects of the platform and user interfaces.

Despite similar goals and the above common characteristics, emerging comparative studies show that national approaches to achieving these goals differ significantly (Priestley et al., 2021). The differences include who initiates curriculum (re-)development and who is represented in development committees/teams, the timeframe and periodicity of revisions, the use of research and other data/evidence, the degree of continuity or discontinuity with the curricular tradition, etc. (van den Akker, 2018). In some cases, the development of new curricula for different levels of education takes place independently (sequentially), but some countries have developed new curricula for the entire initial general education. The approach to the subject curricula may also vary, as, for example, the digital skills curriculum is likely to require more frequent changes. Also in the field of technical and vocational education and training, the necessary revisions tend to be more frequent, the curriculum needs to be more flexible, and the involvement of employers and/or unions in its quasi-permanent revision is crucial.

Returning to similarities, development/revision is often hijacked by politicians or interest groups, and the attention of the wider audience gets focused on some specific aspect, such as the way the national past is presented in the curriculum. Van den Akker (2018) notes that the time needed to develop/revise a curricular framework varies greatly, from about two to eight years, the average being a framework of around six years. If the implementation and some preparatory phases are included, we reach the figure of about nine years. Clearly, the time scale of curriculum development exceeds the usual length of the election cycle, and politicians may be tempted to speed up the process so that positive effects can be reported within a single election period.

Moreover, curriculum change usually takes place simultaneously with the enactment of other educational reforms or policies that influence or even inhibit curricular processes. The larger and more complex the system, the greater the need to devote a shared understanding to building a new curriculum, both within and across levels (Pietarinen et al., 2017). To increase the legitimacy and ownership of the reform, some form of consultation with relevant actors is now an integral part of all stages of development. Various social networks or dedicated internet environments are sophisticatedly used for these consultations, but the real level of involvement of key groups such as teachers or parents seems to remain limited. It is usually easy to get a massive input on social networks quickly, but its representativeness is questionable and distilling a clear vision could be almost impossible. With cultural wars raging and the growing fragmentation of both the general public and professional communities, the future development of new frameworks could turn out to be mission impossible.

The Netherlands may serve as a case of a country where long-term and systematic reflection on curriculum development has been carried out (Thijs and van den Akker, 2009; Handelzalts et al., 2019) and both academic researchers and curriculum development around the world often draw on the work of Dutch authors. At the same time, even such a commitment to capacity building for design processes does not guarantee a smooth course of concrete curriculum changes (as the example of the most recent revision shows). The case of the Netherlands shows that even stabilized democracies have problems (re-) developing curricular frameworks and the whole process can take a longer time in comparison to the original estimates (Nieveen and Kuiper, 2021).

As noted above, in the 19th century, curriculum development was both a facilitator of the emergence of the nation-state and a reaction to it; in the 21st century the new "national" curricula are in a similar relationship to globalization (Lingard, 2018). Curriculum development can also be understood as a case of the diffusion of policies (Steiner-Khamsi, 2012). Globalization produces new relationships between the various levels at which curriculum development takes place, but they are most appropriately described not as "nice" logical models, but post-bureaucratic structures that are polycentric, transnational, and with a great diversity of actors involving the private and public spheres (the "reform industry"). England could be an example, with the transnational commercial Cambridge Assessment project originating from academia having been linked to the recent re-development of the national curriculum.

Above and beyond the educational policy realm, major social and political transitions frame some curricular revisions, e.g., in post-colonial settings. The transition to democracy and a market economy posed a great challenge for the development curricula in the post-Communist countries (Janík et al., 2020). Unfortunately, it seems that before this process could be completed, new revisions were launched in several countries aimed at suppressing liberal values in favor of national and conservative ones. Curriculum designers are also facing specific challenging situations in bicultural and multicultural settings, (post-) conflict environments and fragile states.

Curriculum trends are constantly evolving, but the capacity to take over and implement them in some countries is limited or borrowed innovations are entering educational practice at a time when they are already being revised or abandoned in the countries of their origin. Arguably, not all nation-states are able to produce quality original curricula (Ramirez and Meyer, 2002), but in some subjects (such as history or often the national language) they have no other choice.

Curriculum development infrastructure and capacity building

Recently, considerable attention has been paid to the importance of building the capacity needed for the active involvement of teachers in curriculum development (e.g., Pieters et al., 2019). Somewhat paradoxically, we know far less about how to build adequate capacity or agency at the macro and meso levels and what support structures there should be. In many European countries, for example, there are permanent agencies whose key role is to develop or revise national curricular frameworks (e.g., in the Nordic countries). Elsewhere, on the other hand, ad hoc teams, sometimes under the auspices of a prominent figure in academia or politics, are entrusted with this task by governments. In the United States, non-governmental actors—professional associations—play a key role in setting subject standards, while—according to the official narrative—the state governors prompted the creation of literacy and numeracy standards. However, it is possible that the real curriculum development processes that take place behind these seemingly different structures and arrangements are quite similar (see above).

In any case, three types of expertise defined above should be represented in the development team/agency: substantive knowledge (related to specific disciplines/subjects); understanding of the broader socio-political contexts of schooling and the effects of education, and the technical-professional knowledge and skills necessary for leading the processes of actual curriculum development (Kuiper et al., 2004).

The political nature of curriculum development has long been recognized. However, it is clear that bureaucrats are also entering the design processes in government agencies. Unlike the role of teachers and politicians, little is known about how design processes are affected by the (potentially self-interest-serving) behavior of civil servants. Another related question somewhat neglected by the research so far is the financial side of curriculum development and, more generally, the role of material flows (a welcome exemption being Dempsey et al., 2021). For example, curriculum development in Central and Eastern European countries has in several cases been influenced by the intention to draw on European funds (external funding-driven reforms).

Conclusion

Despite all the criticism, normative models of curriculum development continue to emerge. They can be useful especially where the development takes place relatively close to the learners and involves a small, relatively homogeneous group of actors. Very similar principles are often rediscovered under different names, and many approaches can be related either to a product (ends-means) model or a process (encounter) model of curriculum development.

Models look so elegant compared to the reality. We can read in them the modernist belief that such a new, fully rational restart of education is possible. The real world of curriculum development at a system level seems to be far more chaotic. Therefore, when creating a model of curriculum development, the educationalist is in danger of believing his/her own construct. Longstreet and Shane (quoted by Marsh, 2004) argue that the curriculum is not some elaborate structure, it is a historical coincidence. It was not developed to achieve any clear set of goals, but rather gradually emerged as the complexity of education increased. We would need more empirical research to better understand these processes.

At the macro level, we now encounter review, revision and renewal processes that try to adapt the historically sedimented curriculum to current requirements, making it also more socially just and inclusive (Young, 2008; Young and Muller, 2010). Supra-level transnational actors such as the OECD, the World Bank, UNESCO, or the EU tend to be directly or indirectly involved, e.g., by producing background papers (e.g., OECD, 2015). Explicit international benchmarking or less obvious borrowing processes become a usual part of such exercises (Baek et al., 2018). Much attention is paid to the transparent communication of all steps, an emphasis on broad participation, and the strengthening of ownership, and the planning of curriculum implementation and teacher support are necessary from the beginning of development activities. However, such a complex enterprise carries with it the risk that the traditional curriculum development issues of the selection of educational content and its organization will be somewhat neglected.

Introduction

Curriculum studies is the nexus where educational thinking and practice meet, by this I mean it links thinking across traditional humanities, social science, philosophy and psychology. Curriculum studies is concerned with what we define as knowledge or content, with discussions around whether knowledge can be defined as being powerful knowledge or knowledge of the powerful in a push away from knowledge relativism (Young, 2008, 2010; Wheelahan, 2010; Rata, 2012, 2019; Wahlström, 2016). Deng (2022) calls for us to think about the concept of a knowledge-rich curriculum. Curriculum studies as a field has gone through a crisis of identity from the assertion by Schwab in 1970's that the field was moribund, to talk of the field being in crisis (Wheelahan, 2010) to a call from Priestley and Philippou (2019) to put curriculum at the heart of practice. Deng in his critique of developments in the discipline of curriculum studies contends that there is an evolution of practice away from classroom concerns to a wider cultural studies perspective "that encompasses literally any topic pertaining to politics, culture, society, environment, technology and human existence" (2018, p. 692). Taking all this into consideration clearly the role of curriculum studies in teacher education is complex. Teacher education strives to make new what is familiar about schooling, what Popkewitz (2014, p. 3) calls "denaturalizing" what seems natural. Pinar (2004, p. 25) calls for teacher education that takes "the generative roles of creativity and individuality in teaching" serious to push against a de-professionalization of the practice. To do this Pre Service Teachers (PSTs) need to develop curriculum thinking (Deng, 2020), they need to develop the capacity to be curriculum makers (Priestley et al., 2021; Deng, 2020) and be afforded the agency (Priestley et al., 2015) to negotiate spaces within sites for curriculum making (Priestley et al., 2021).

The role of the teacher in curriculum has begun to change with the emergence worldwide of new forms of curriculum development and policy, which explicitly reposition the teacher as an agent of curriculum change and active maker of the curriculum in local settings (see for example Priestley and Philippou, 2018; Priestley and Biesta, 2013). Curriculum implementation requires more from the teacher and it demands more from schools than what was historically the case (Dempsey et al., 2021). We see examples of these new forms of curriculum in Ireland in the Junior Cycle Reforms (NCCA, 2015), Curriculum for Excellence in Scotland (Scottish Executive, 2004) and more recently the curriculum reforms in Wales. What is notable about these reforms is how they position the teachers as curriculum interpreters, implementers, makers and enactors. This is a new role for some teachers who traditionally worked with a system that relied on input regulation with tightly prescribed curriculum documents defining what to teach and, in some cases, how to teach content (Nieveen and Kuiper, 2012). While we have moved on from the concept of a teacher proof curriculum, Priestley and Xenofontos (2020) talk about the need for schools to be sites where curriculum questions are posed and addressed constructively, and I would add in some cases where curriculum policy needs to be opposed or advocated for. This role of teachers as curriculum makers is not altogether new as arguably teachers make curriculum in their daily pedagogical decisions, as Bruner (1999) reminds us that pedagogy is never innocent, it carries its own messages. Clarification of the concept of curriculum has the potential to deepen our understanding of/insights into pedagogical processes. Such enrichment has a special relevance for teacher education.

Clearly this role for teacher as curriculum maker needs attention in teacher education courses. Curriculum making requires PSTs to relate theory and practice in their university learning and in their practicum experience, the boundaries between both sites are blurred. Priestley and Philippou (2018) contend that curriculum making occurs

Across multiple sites, in interaction and intersection with one another, in often unpredictable context-specific ways, producing unique social practices, in constant and complex interplay, wherein power flows in non-linear ways, thus blurring boundaries between these multiple sites. (p. 154).

For the purposes of this Chapter, I will use Priestley's (2019) definition of school curriculum as "the multi-layered social practices, including infrastructure, pedagogy and assessment, through which education is structured, enacted and evaluated" (p. 8). This definition in tandem with the definition of curriculum making above recognizes how curriculum is a social

Fig. 1 Pre service teacher as curriculum maker – complex webs of enactment.

practice, between teachers, between a teacher and their students, between school leaders and teachers, parents and students, policy makers and teachers and so on, there are multiple actors involved in making curriculum. It also acknowledges how curriculum is made in multiple sites, for example, at the policy table, the school, classroom level and individual level, among others (Priestley et al., 2021). This definition also recognizes how curriculum is political, and involves power and occurs across different layers (Priestley et al., 2021). For curriculum change to happen there needs to be alignment between the content or knowledge, the teaching, the learning and the assessment practices (Dempsey et al., 2021). If any one of these are not aligned curriculum making is stifled. Looney (2001) contends that curriculum, assessment, pedagogy and organization are treated in isolation. It is the intersection of these message systems at the school level that is important, and this is often not analyzed. These message systems are central to curriculum making. In addition, it is difficult to address teachers' role in curriculum making without looking at the concept of agency and the ability to exert agency in the sites for curriculum making (Priestley et al., 2015).

In this Chapter, I will outline the complexity of curriculum making for PSTs as they navigate sites where it happens (Priestley et al., 2021), within the policy, programmatic and classroom domains (Deng, 2018, 2020; Doyle 1992), and make judgments on what content/knowledge to teach (Young, 2008; Rata, 2012; Biesta, 2015; Deng, 2020), and for what reason (Biesta, 2015; Deng, 2020) while they seek to bring the curriculum alive in fruitful experiences for the students they teach (for example, Shulman and Shulman, 2004; Lambert and Biddulph, 2014; Schulte, 2018). Fig. 1 gives an overview of how the article links the thinking on curriculum making within the Initial Teacher Education (ITE) space.

Curriculum making and educational change

Across the world there are multiple actors involved in processes of curriculum reform, often with conflicting ideas and priorities. These actors can represent cultural, political or epistemological stances, or a combination of all three (Slattery, 2013). Apple writing in 2006 from the perspective of the USA, reminded us that education is a site of crucial struggles over authority and identity and over what it means to be educated. Issues such as an audit culture and privatization are even more pertinent today considering new forms of curriculum development where there is a push for skills linked to the economy, personalization of learning, a move to output regulation, datafication and a marketization of education (Lingard, 2011; Lingard, 2013; Biesta, 2015; Winter, 2017; Tahirshylaj and Wahlström, 2019). These big issues are not easy to address, they are complex. Curriculum has a major role to play in addressing them. At the core of each new wave of educational change is the curriculum. Curriculum development, implementation, evaluation and curriculum policy development and analysis are central to educational change (Connelly and Xu, 2010). Without changing the curriculum there can and will only be structural change. We have seen this in Ireland with successive efforts to change the experience at lower secondary for students (Gleeson, 2012). Until the present reform there was little success (Smyth and McCoy, 2011). This was due in part to a lack of alignment between teaching, learning, assessment and curriculum content (Dempsey et al., 2021). Without considering the variety of ecological factors in schools, policy change is doomed to fail or at best be partially implemented (Priestley et al., 2012). In 2018 Apple still had concerns for the field of education and in particular the decisions around curriculum policies and practices. He wrote.

With neoliberal, neoconservative, authoritarian populist, and new managerial forces increasingly occupying the space of real policies and practices, we have little voice in the public debates over the realities of schooling and the decisions of curriculum policies and practices. The field of education deserves more.
(Apple, 2018, p. 689).

Deng (2020) building on the work of Doyle (1992) describes three levels of curriculum making, the policy, the programmatic and the classroom level and in doing so he highlights how the teacher can exert power and have voice in education. Curriculum making within the policy level is concerned about what schooling should be with respect to society and culture. It is about the big questions such as what is education for? (see Biesta, 2015), in this domain curriculum making is viewed as “something with social, economic and political meaning and significance” and contributing to the well-being of society (Deng, 2011, p. 547). In the programmatic context curriculum making is concerned with school subjects and program content. This is what some term the official or written curriculum (see van den Akker, 2003). Curriculum making at the classroom level is how teachers transform the official or programmatic into “educative experiences for the students” (Deng, 2020, p. 31), where the programmatic curriculum “invites critical testing rather than acceptance” (Stenhouse, 1975, p. 142). This central role for teachers in curriculum making in unlocking what “*curriculum potential* a material has depends on how the teachers uses the material” (Deng, 2011, p. 538 emphasis in original). It is important to note that the choices teachers and PSTs make is grounded in knowledge that is personal (Clandinin and Connelly, 1988; Haraldstad and Kristiansen, 2020) and entails professional judgment (Goodson, 1997; Biesta, 2015).

Priestley et al. (2021, p. 12) posit that curriculum making occurs within and between layers or sites of social activity and is defined and determined by the nature of the curriculum making activity rather than the site at which it occurs. Table 1 provides a typology for the sites where curriculum making occurs, this work by Priestley et al. (2021) builds on earlier work by Thijs et al. (2009) and seeks to move from a linear concept of layers to sites. The influence of transnational curricular discourse at the supra site is more evident since Lisbon in 2000 where education was linked with social policy, labor market and overall economic policy and with the introduction of Open Method Coordination^a (European Council, 2000). This has led to policy borrowing and peer learning, but also to ideation convergence and an obsession, some would say, with global data (Raffe, 2011; Dale and Robertson, 2012; Lingard, 2011). Curriculum is not immune to this supra influence, however, it is not as prevalent as one might first think. Even with all these international data (such as PISA and TALIS) available for comparisons, there is little evidence of it having direct impact on educational policies, curricula and the way teaching and learning are organized in schools according to some commentators (Drent et al., 2013). Some influence can be seen in new forms of curriculum development where key competences or versions of them can be found in most curricula (Gordon et al., 2009; Halász and Michel, 2011; Biesta and Priestley, 2013; Dempsey, 2016).

The question arises as to where in this typology does teacher education exist? Is it between the meso and the micro sites? The policy governing the organization and structure of teacher education programmes rests in the macro space and is influenced by the supra space. Conway and Murphy (2013) contend that the interrelated influences of the European higher education space, education legislation and professional self-regulation policies from local regulatory bodies all exert influence on teacher education. The three interrelated domains of curriculum making described by Doyle (1992) and expanded on by Deng (2018, 2020): the policy curriculum, the programmatic curriculum, and the classroom curriculum are not unlike these sites above. Deng (2010, 2017) contends that these domains are not only inter-related but also inter-dependent, Priestley et al. (2021) talk about the how curriculum making at these sites is complex and multidimensional with porous borders between sites. A key challenge is for PSTs to locate themselves within this curriculum making space and to appreciate how the layers/domains or sites are inter-dependent and influence their professional practice.

Table 1 Sites of curriculum making.

<i>Site of activity</i>	<i>Examples of activity</i>	<i>Examples of actors</i>
Supra	Transnational curricular discourse generation, policy borrowing and lending; policy learning	OECD; World Bank; EU
Macro	Development of curriculum policy frameworks;	National governments; curriculum agencies; teaching regulatory bodies
Meso	Production of guidance; leadership of and support for curriculum making; production of resources	National governments; curriculum agencies; textbook publishers; professional development providers
Micro	School-level curriculum making; program design; lesson-planning	Principals; senior leaders; middle management; subject teams; teachers; PSTs
Nano	Curriculum making in classrooms and other learning spaces; pedagogical decisions	Teachers; PSTs; students

Source: Adapted from Priestley et al. (2021), p. 13.

^aThe Open Method of Coordination (OMC) is an EU policy-making process, or regulatory instrument, formally initiated by the Lisbon European Council in 2000. The OMC does not result in EU legislation, but is a method of soft governance which aims to spread best practice and achieve convergence toward EU goals in those policy areas which fall under the partial or full competence of Member States.

PSTs are in university being inducted into a profession, forming their teacher identities, developing their pedagogical knowledge, developing professional judgment while negotiating what it means to be a curriculum maker. Priestley et al. (2021) describe this complexity of how one needs to negotiate this social activity and;

Operate in education systems as curriculum is made and remade in different settings; as sites of social activity with changing social actors, who are moving between sites, are being present in more than one, or actually becoming a site themselves depending on the social activity they are engaging in (p. 12).

PSTs are straddling the university and the school site, working with social actors in both sites. It is interesting that PSTs or teacher education do not feature in the representations of layers or sites to date. Priestley et al. (2021, p. 14) see this typology as “an analytical tool for understanding how curriculum making occurs and emerges in different contexts” and for this reason is very useful when thinking about the teacher education space. The work of teacher educators with PSTs in the university setting around curriculum could be construed as micro curriculum making, this is where the PSTs either work individually or in teams to plan topics for teaching when in school. It is both linked back to the macro site through subject specification, curriculum planning materials and supporting documentation and the nano site of the classroom where the teaching will occur.

Curriculum making and teacher education

The term curriculum means different things to different people depending very much on their context and the site they are working in. Deng (2017, p. 1) contends that “the matter of defining curriculum is in a state of disarray.” In his 2017 paper Deng provides multiple definitions of curriculum and teaching and in doing so not only highlights the complexity of the area but also offers a promising way to revitalize curricular and pedagogical theory as applied to practice in schools and classrooms in context. In recent years scholars including Deng (2017) and Priestley (2019) have provided definitions that aim at dealing with this complexity. Building on the definition for curriculum provided by Priestley (2019, p. 8) as “the multi-layered social practices, including infrastructure” it is important to unpack what the concept of multi-layered means in the context of teacher education. Deng (2020) provides a succinct description of how curriculum thinking across curriculum policy, curriculum planning and classroom teaching is needed for curriculum making by teachers.

Curriculum planning at the institutional level entails an interpretative, deliberative process within a particular social context, with specific groups of learners in mind. Through this process, various types of knowledge are selected and organised into content in the light of their potentials for the cultivation of human powers. In the classroom a teacher interprets and enacts the content of a school subject – embedded in the institutional curriculum – to create “fruitful meetings” between students and content that give rise to the cultivation of human powers (p. 91).

Curriculum making in the context of this chapter is seen as a social practice, where each actor draws on “personal practice knowledge” (Connelly and Clandinin, 1988, p. 25), linked to the concept of reconstructing the past and the projective intentions for the future within the cultural, structural and material of the present (Priestley et al., 2015; Wallace and Priestley, 2017). Cornbleth (1990) contends that curriculum is contextually shaped. Understanding curriculum making and agency in this way helps us to acknowledge the many dilemmas experienced by the PSTs as they negotiate and use this personal practice knowledge in developing curriculum within the dominant social, cultural, political and institutional narratives structuring educational contexts (Cornbleth, 1990; Goodson, 2003; Priestley et al., 2015). In the Irish context we are working within an education system that has a history in the post-primary sector, at least, of predominantly top-down linear curriculum development, with a high stake externally assessed examination leading to little space for curriculum making at the micro and nano domains (Banks and Smyth, 2015). However, the process of curriculum development in recent years has changed with more emphasis on research, consultation and working with schools and curriculum specifications that encourage local interpretation (Dempsey et al., 2021).

Loughran (2006, 2010) reminds us that students of teaching have a natural desire to learn about teaching, however, he asserts that learning to teach about teaching is confusing, full of uncertainty and complexity. Learning how to be a curriculum maker amid this complexity is no easy task but an essential one. Biesta (2015) reminds us that “the point of education is that students learn something, that they learn it for a reason, and that they learn it from someone” (p. 76). Deng provides an excellent synopsis of this vital role the teacher plays in curriculum making.

That teaching is an ethical and intellectual undertaking that is vital for social reproduction and innovation, human development and the flourishing of students – and for which content is an essential resource. And teachers, being (as they are) at the heart of such an undertaking, are curriculum makers (or theorists) who must grapple with the intellectual and moral questions of what content should be taught, why it should be taught and how it should be taught within a particular classroom context (2020, p. 65).

This central role for teachers is also echoed by Biesta (2015) when he describes teachers as educational professionals that should have scope for judgment and discretion in how, why and what they teach. Schwab’s (1978) four commonplaces recognizes the

teacher as central to curricular decision making further supporting the central role the teacher has in bridging the gap between the curriculum content and the experienced curriculum of the student.

Current teacher education reforms emphasize teachers learning more disciplinary knowledge so that they can become more competent (Conway and Murphy, 2013). Some see this as a result of the neoliberal push for benchmarking, standards and numerical ranking (Lingard, 2011; Popkewitz, 2014; Sellar and Lingard, 2014). The thinking is that if teachers know more, they will be better teachers. There is some merit to this kind of thinking, see, for example, the large body of research on Pedagogical Content Knowledge (PCK), a concept first mooted by Shulman (1986) and later expanded to include Mathematical Knowledge for Teaching (MKT) the mathematical knowledge required for teaching mathematics (Ball et al., 2008) and Technological Pedagogical Content Knowledge (TPCK) the knowledge needed to integrate technology into teaching (Mishra and Koehler, 2006) among others. PCK and associated concepts have been the subject of intensive investigation (Depaepe et al., 2013). Seidel and Stürmer (2014) state that one of the main aims of teacher education is to help teachers acquire integrated knowledge of theory and practice. However, Deng (2020, p. 60) contends that PCK needs to be expanded to include “curriculum thinking, alongside specialist curriculum knowledge” for teachers to identify and interpret the content and unlock its potential. The important concept here is how teachers link their knowledge of their discipline, with their knowledge of pedagogy with their understanding of the individuals they are teaching in the context of their classroom at a particular time while acknowledging the influences from within and outside the classroom. This is what curriculum making entails in each moment in teaching, see Fig. 1.

Phelps and Lee (2003) contend that teachers tend to revert to teach in a way which they themselves were taught. For example, Conway and Murphy (2013) found that PSTs working with schools in reform-oriented mathematical contexts are presented with several dilemmas. These are the mismatch between their experience as a secondary school student studying mathematics, their experience as a university student studying mathematics and education, and their experience as a pre service teacher on placement in a school. The impact of these three types of experience on how PSTs construct, deconstruct and reconstruct their professional identities is well documented (see for example Flores and Day, 2006; also, Osgood, 2010 with early childhood educators). Part of this development of professional identity is how PSTs approach curriculum, with what Olson refers to as “unique narratives of experience” (2000, p. 173). Gholami et al. (2020) refer to an “internal dialog” that PSTs established between their personal and professional selves while observing real conditions of students in schools, this dialog contributes to their construction of professional identities. This dialog, discourse and language is crucial to the process of constructing and construing the world and self (Popkewitz, 2014) and is imperative to PSTs developing curriculum making capacities. Teacher education can underplay and misrepresent the process of curriculum making and the complexity of teaching as a social process (Priestley and Philippou, 2018). As stated earlier the complexity of developing this specialist curriculum knowledge (Deng, 2020) and curriculum thinking for curriculum making (Deng, 2022) in teachers’ education is influenced by personal practical knowledge and personal agency (Priestley et al., 2015). Priestley and colleagues describe agency as;

An emergent phenomenon- as something that is achieved by individuals, through the interplay of personal capacities and resources, affordances and constraints of the environment by means of which individual act (p. 19. emphasis in original).

If we apply this thinking on agency to PSTs, we can see how their life and histories are intertwined in their personal practical knowledge found “in the person’s past experience, in the person’s present mind and body, and in the person’s future plans and actions” (Connelly and Clandinin, 1988, p. 25). Clandinin and Connelly (1992) drew of Dewey’s (1938) work on experience and Schwab’s (1978) four commonplaces, that is, teacher, learner, subject matter and milieu and conclude that curriculum might be viewed as “an account of teachers’ and students’ lives together in schools and classrooms” (p. 392). They see curriculum making as something that is dynamic, experienced in relation to others with as esthetic and moral component. This view is also echoed in Deng’s (2020) concept of cultivation-via knowledge and in Priestley et al. (2015) conception of agency. For Deng (2020), there are three propositions for cultivation-via-knowledge platform, one is a vision of education, two an attendant theory of knowledge and three, a “theory of content which serves to inform curriculum planning and classroom teaching” (p. 91). However, Gleeson and O’Flaherty (2014) caution that there exists a theory/practice dichotomy for PSTs as they grapple with the own beliefs and that of schools, teachers and the external environment. Also some argue that teachers and PSTs need to develop “the complex skill of understanding the double-speak of policy documents” (Schulte, 2018, p. 634).

Space for curriculum making in initial teacher education (ITE)

From the earlier discussion in this chapter we see that curriculum making and agency is contingent on personal capacities but also dependent on cultural and structural working conditions (Priestley et al., 2015). For PSTs on their Initial Teacher Education (ITE) course the space for curriculum making is crucial as they navigate the cultural and structural conditions of the university and then also to the school where they have their practicum. Nieveen and Kuiper (2012) in their cross-case analysis of curriculum regulation provide a good overview of how the pendulum swings from tight to loose regulation in curriculum. They describe what this regulation means.

“Curriculum regulation” reflects a government’s intention to prescribe the high-fidelity implementation of directives at the input level (goals and contents, in terms of “goals to attain”) and at the output level (modes of assessments and examinations). Those prescriptions imply that the room for site-specific curricular choices is restricted. On the other hand, “curriculum deregulation” reflects a government’s intention to refrain from prescription and control at the input and output level by stimulating school-based decision-making “through soft tools and systems” (p. 359).

At the heart of curriculum deregulation is a culture of trust in schools and teachers having the professional freedom to make site-specific interpretations of curriculum specifications, in essence a desire to provide space for curriculum making (Priestley et al., 2021) and professional judgment (Biesta, 2015). In Scotland researchers found that pressures of attainment and other accountability mechanisms acted as a barrier for teachers to exert professional agency (Wallace and Priestley, 2017). Clearly curriculum policy can afford teachers and PSTs greater flexibility, autonomy and space to be curriculum makers, but must do so with an acknowledgment of local ecologies and the capacity and agency for curriculum making.

For PSTs to move away from a transactional classroom environment to one where they are curriculum makers they need to link their practice to theory and in cases to many theories. For example, if a PST wants to incorporate dialogical teaching into their mathematics class, they might draw on theorists such as Dewey (1938), Alexander (2017), and Ball (2000) including others. In planning for a class that incorporates dialogical teaching they are consulting philosophy of education, sociology of education and learning theories and making decisions around knowledge selection (Young, 2010; Lambert, 2018), select tasks for teaching and assessment (Dempsey and O'Shea, 2020). Schulte describes how this classroom enactment further interacts with various ideas and practices as follows:

They engage with school policies, school and teacher organization, and various forms of teacher training (both pre-service and in-service); the kind of teaching guidelines and materials at disposal (such as various national, regional, and local curricula and textbooks); those again are partially an outcome of academic research and discourse, as well as of various forms of policy-making among political bodies 2018, p. 626.

This classroom practice in schools, in the words of Deng (2018) requires our PSTs to use theories and models in “an eclectic, critical and innovative manner” rather than rely on one theory or doctrine. It calls for greater conceptual clarity between curriculum and pedagogy (Lambert and Biddulph, 2015). This use of theory and curriculum thinking (Deng, 2020) and teacher judgment is central to what it means to be a professional (Biesta, 2015; Deng 2020).

Conclusion: key concepts in curriculum making, agency and curriculum literacy for PSTs

Curriculum making entails three inter-related processes. The first is selection of content to teach. As stated earlier this can be highly prescribed in subject specifications or leave space of professional judgment. Regardless, the PST must make a judgment on what knowledge/content they will teach. This may include powerful knowledge (Young, 2010), skills or competences and attitudes or dispositions. Lambert reminds us that the curriculum is about knowledge selection, but teachers need to work with this knowledge and ensure that students are meaningfully engaged with it (2018, p. 14). The PSTs then makes decisions on how to teach the knowledge/content including decisions on the type of tasks to use (Dempsey and O'Shea, 2020), the kind of pedagogical experiences they will set up for their students and how they will assess the learning. At the heart of these decisions is relationships, the relationship between the PST and their discipline (subject), their students, colleagues and community. The pedagogical decisions are not only part of what happens in the classroom but “they further interact with various ideas and practices” from other sites of curriculum making (Schulte, 2018, p. 626; see also Priestley et al., 2021). Linking to the purpose of education they must teach this content for a reason. What is critical is the human interaction not just a knowledge transaction exercise.

Curriculum making entails deliberative decision-making at the planning stage and in the work within the classroom. These decisions are linked to the purpose of education and to the needs of the students within a specific context of a school or classroom it is both practical and projective (Priestley et al., 2015). Deliberative decision-making requires the use of theory to illuminate and interpret specific issues and problems (Deng, 2018) and involves fundamental questions of teachers thinking and teachers doing (Connelly and Clandinin, 1988). PSTs need to be able to reflect on practice within the context of their schools, their classes and their students. In doing this they bring with them their past and present educational experiences and have a focus on the future, the way they want to develop as teachers, how they wish their practice to be embodied in their professional career. What can be challenging for PSTs is how they grapple with the disconnect between their personal experience of education and the theory and practice they are being taught in their university pre service teacher education course. Equally the mismatch between their university course material and the observed practice in schools can cause dissonance. The school can be a “world of conflicting ideas and actions” (Teo, 2012, p. 672; see also Gleeson and O'Flaherty, 2014).

For PSTs to engage with curriculum making in their ITE courses, they must see themselves as having agency within the sites for curriculum making (Priestley et al., 2021), they must be provided with opportunities to develop curriculum making capacities. One such capacity is relating the theory to practice “in an eclectic, creative and innovative manner, for the purposes of constructing theory that matters in practice and in the world of schooling” (Deng, 2018 p. 707). Another is making judgments about appropriate content, pedagogy, organization of the classroom and so on (Lambert and Biddulph, 2014; Biesta, 2015; Deng, 2017, 2020). Finally PSTs need to become curriculum thinkers where they think about the what and why of teaching and make decisions, judgments on the educational potential of content (Deng, 2021; see also Biesta, 2015). Building on the work of Biesta on the three purposes of education that of qualification, subjectification and socialization, PSTs need to keep these “in an educationally meaningful balance” (2015, p. 78). This is a complex task that requires professional judgment. PSTs need to know “the learner” and become aware of the “educational milieu” is a major challenge. Teaching is a social practice and us working in teacher education need to recognize that something like a teaching experience during ITE is rooted in one context but that the chances are high that the PSTs will progress to

work in very different contexts. Thus, being able to listen to and to know the learner and, indeed, the educational milieu (school culture and so on) is a vital, and difficult skill to develop. At best we strive to “denaturalize” the taken for granted and to open up the space to engage with these curriculum questions (Popkewitz, 2014).

Priestley and Xenofontos (2020) tell us that we need to focus less on excellent teachers and more on excellent teaching, and in doing this we avoid unnecessary dichotomies and see different curriculum practices as interrelated. Fig. 1 strives to bring some of the complexity of curriculum making and thinking together. One of the purposes of education is “to enfold within each present moment the past, the present, and the future so that our lives will be illuminated with deep understanding” (Slattery, 2013, p. 90). It is the enfolding described here that makes ITE and curriculum making such a complex but rewarding endeavor.

Introduction

In the present article, curriculum as an object of activity is the framework through which curriculum making is explored from the perspective of academics. Curriculum researchers have repeatedly agreed that the concept of curriculum has various interpretations in higher education research and practice (e.g., [Annala et al., 2016](#); [Coate, 2009](#); [Fraser and Bosanquet, 2006](#); [Knight, 2001](#); [Krause, 2020](#)). If the understanding of curriculum is not shared, actors in one specific curriculum change context may see the object of the activity from contradictory perspectives, which may result in contradictory actions and outcomes ([Annala and Mäkinen, 2016](#)). Depending on the scale of the curriculum making and the role of the actors, the consequences may be different.

Curriculum making is understood here as an intentional, dynamic and contradictory process that is always situated in a certain cultural, historical, societal and political environment. Regarding the contemporary environment in curriculum making in higher education, [Krause \(2020\)](#) has identified three “vectors of change” that are shaping higher education curricula: national and international political, economic and labor market forces; universalization; and the influence of technology. The role of national policy and regulatory frameworks varies; however, today in OECD countries especially, student employability, quality standards and institutional accountability have a noteworthy impact on shaping curricula ([Krause, 2020](#)). For example, the harmonization of European higher education degrees through the Bologna process ([European Commission/EACEA/Eurydice, 2018](#)) was executed through higher education policy, but in the end, it manifested in different ways in curriculum making in the local discipline-specific work contexts of academics ([Karseth, 2006](#); [Wihlborg and Teelken, 2014](#)).

The second vector of change is universalization, which refers to the widening access to university education ([Krause, 2020](#)). The diversity of the student body, with different knowledge, cultures and experiences, shapes the curriculum ([Krause, 2020](#)). For example, in South Africa, structural injustices and the equity of access and outcomes are topical in curriculum transformation, as the deficit view has predominated instead of recognition ([Luckett and Shay, 2020](#)). The question of knowledge is also significant here. Originally, [Gibbons et al. \(1994\)](#) defined mode 1 and mode 2 knowledge, mode 1 referring to more traditional forms of knowledge building and research in universities, which is hierarchical and specialized, whereas mode 2 knowledge is associated with industry, innovation and government, emphasizing knowledge development in interdisciplinary collaboration and the applicability and usefulness of knowledge ([Yates et al., 2017: 19](#); [Young, 2013](#)). The widened access attracts students, for example those with a nonacademic family background and who may be more engaged with working-life-oriented and integrated curricular knowledge (mode 2). Yet all the students in higher education should have access to powerful forms of knowledge (mode 1), because access to abstract theoretical knowledge is a precondition to joining the important discussions in society and to democracy ([Shay, 2013](#); [Wheelahan, 2010](#)).

All fields draw on some mix of conceptual knowledge and know-how of various kinds, but some disciplinary fields are more vocational and some more “truth-seeking,” as the higher education institutions also are. Nonetheless, in curriculum trends, the balance has moved from mode 1 knowledge toward mode 2 knowledge ([Lindén et al., 2017](#); [Yates et al., 2017: 20](#)). This is visible in the third vector of change, the advancement in technology and the simultaneous emphasis on industry-aligned learning outcomes ([Krause, 2020](#)). This has emerged as the unbundling of formal curriculum and the rise of microcredentials, digital badges and nano-units that shape the curriculum toward a “buffet table” service without curriculum coherence ([Cliff et al., 2020](#); [Krause, 2020](#)). Thus, the second and third “vectors of change” are linked to the first one, the political, economic and labor market forces around higher education curriculum.

These trends are very different from the traditional tasks and cultural norms of higher education curriculum, described as aiming to provide opportunities for purposeful, intended experiences of complex learning with indeterminate and non-linear nature that are “not easily reducible to precise statements predicting what the outcomes will be” ([Knight, 2001](#)). Wang also states that higher education should not be a pre-given way on a map in which the student is prepared to pursue professional competence and employability; instead, the goal of higher education is to educate a student to be “a cartographer to create his or her new life” (2015: 1558) and to invite students to “explore strangeness, thereby promoting their curiosity and assisting them in accommodating a future creatively” (2015: 1557).

Fig. 1 Analyzing curriculum making as an activity system. Source: Engeström, 1987: 78.

Being aware of this contemporary environment of higher education curriculum, curriculum making is approached here as a multi-voiced and multilayered activity system (Engeström, 2000; Foot, 2014). The aim is to analyze curriculum making in higher education with the help of concepts from activity theory (Engeström, 1987). Activity theory is used as a broad framework by which it is possible to pay attention to micro- and macrolevel elements in curriculum making. Cultural-historical activity theory has different emphases and approaches as well as different generations. This paper is built on the concepts of the activity system modeled by Yrjö Engeström (1987: 78) as illustrated in Fig. 1. The activity system has six components, of which the first three are more visible: a subject (actor), an object and tools. Tools are employed by the actors to work toward the object of action and to achieve the desired outcome (Foot, 2014). The three other components—rules, community and division of labor—are less visible social mediators of activity (Engeström, 1999).

Inner contradictions between the six components create constant transformation and reconstruction and are a source of development and change (Engeström, 1999; Foot, 2014). Correspondingly, curriculum making is often depicted using terms like “development,” “reform” and “change” in the strategic discourse (Krause, 2020), but terms like “struggle” and “bargain” appear when academics describe their experience (Annala et al., 2020).

Activity in the system requires subjects (actors), referring to “the individual or subgroup whose position and point of view are chosen as the perspective of the analysis” (Engeström and Sannino, 2020: 5). Traditional curriculum making is often led by experts working inside the university system, but participatory approaches have broadened the co-ownership toward different stakeholders, such as educational developers, managers, students, representatives of the world of work and policy-makers (Alexander and Hjortso, 2019). In the following, the perspective of academics as subjects (actors) in the system is emphasized. During the last ten years, in our research group, we have completed several qualitative studies on curriculum from the perspective of academics. These studies are used here to illustrate curriculum making as an activity system.

Curriculum as an object of activity

The concept of “object of activity” is regarded to have a key role in the activity system (Leont’ev, 1978). Engeström and Kerosuo (2007: 337) state that “the object embodies the meaning, the motive and the purpose of a collective activity system.” According to Foot (2014), the object is comprised of three facets: a thing-to-be-acted-upon (e.g., curriculum), an objectified motive (e.g., developing or reforming the curriculum) and a desired outcome (e.g., superior quality of teaching and learning). Objects of activity have been described as a “horizon of possibility” (Blackler, 2009: 29) and as a “raw material or problem space at which the activity is directed” (Engeström and Sannino, 2020: 5).

When thinking of curriculum making, the desired outcome and “horizon of possibility” varies among academics. Based on interviews (N = 45) of teachers at a research university and university of applied sciences, representing a range of different disciplinary fields, we identified nine different objectives for curriculum development (Mäkinen and Annala, 2010a, Fig. 2). Our analytical framework relied on a schema developed by Barnett and Coate (2005), where three curricular objectives concern students’ knowing, acting and being. Knowing refers to the core knowledge of the subject or disciplinary field in question, acting refers to the kind of actions and practices, such as “acting like a dentist” or “thinking like a sociologist,” which the student is expected to acquire. Being has to do with the student’s identity and personality, “who I am” and “what kind of relationship I have with the knowledge and knowing” (Barnett and Coate, 2005.) In our analysis, we also used Bernstein’s (1996) concepts of introjection and projection, described as starting points of university education. Introjection refers to the construction of curriculum on the basis of internal disciplinary interests (e.g., the subject taught), whereas curriculum development on the basis of external demands (e.g., competence

Fig. 2 Comprehensive curriculum framework Source: Mäkinen and Annala, 2010a: 12.

demand in working life) is called projection (Bernstein, 1996). We found external and internal objectives for curriculum development but also interconnected views between them.

At one extreme, the aim of curriculum emphasizes the external demands; it is reaction to the contemporary knowledge requirements of the society and aims to produce competences relevant to employment and to make a student “a fit product” for the market. At the other extreme, curriculum is made for the university and teachers themselves, to fit and preserve their areas of interest (cf. Shay, 2011), with a fragmentary and subject-specific approach without connection to the world outside. If one teacher wants to make a curriculum so that it retains teaching positions (requirement to have “my course” in the curriculum) and another aims to produce knowledge relevant to working life (giving the authority to outside stakeholders), the contradictions emerge (Mäkinen and Annala, 2010a.) These oppositions reflect, on the one hand, neoconservative traditionalism, emphasizing the given body of knowledge that is transmitted through educational institutions, and on the other hand, technical-instrumentalistic curriculum policy, where curriculum is seen as a way to direct the students toward the needs of the economy (Young, 2008). The oppositions also make visible the layers of higher education history influencing the present-day approaches (cf. Engeström and Sannino, 2020).

If contradictions in the activity system are regarded as a source of development and learning, the interconnected view could also be described as such. Remaining true to the core of a given discipline, but being conscious of what the world is outside the university, was taken as an opportunity to make a difference to the world outside and not just to follow the market voices (Annala and Mäkinen, 2016; Mäkinen and Annala, 2010a). In that case, mode 1 and mode 2 knowledge were combined (cf. Gibbons et al., 1994). Even though this could be a happy end to a story, it is important to note that only some of the informants shared the interconnected view and did not necessarily collaborate, as they were from different faculties. The object of activity remains various in the actual curriculum making process if it is not consciously shared and made meaningful inside the local community (Annala et al., 2021).

As the above-discussed study was a local case study representing teachers, the practitioners, in curriculum making, I will next look at the curriculum researchers’ perspective on what the object of activity in curriculum making is, as it offers a more global view of the object of activity. A few years ago, we did a systematic review of how curriculum is approached in research articles in higher education journals (Annala et al., 2016). Following curriculum theoretical ideas, we used as our reference point the traditional distinction of understanding curriculum as syllabus, product, process and praxis (Grundy, 1987; Kelly, 2009/1977). When we looked more closely, the 62 analyzed articles represented fundamental differences in their orientation toward two core themes: knowledge and ownership. This analysis brought to the fore the power relations and the nature of the outcomes, as if students were empty spaces to be filled or as if they had ownership in the process. What we found was that curriculum was conceptualized as (1) controlling of contents, (2) producing competences, (3) negotiating of potentials and (4) empowerment. If curriculum is seen from the perspective of control (e.g., mapping the knowledge and skill gaps defined by experts from industry) or from the perspective of empowerment (e.g., creating culturally sensitive curriculum or paying attention to students’ access to powerful forms of knowledge), the object of the activity is very different.

Sannino and Engeström (2018) state that the object of activity is difficult to define for the participants, as it cannot be reduced to conscious goals and actions. An important distinction here is the difference between action and activity. As the actions are directed toward short-term goals, at a given moment, in each action, the object of activity evolves historically and culturally, giving space to interpretation, personal sense making and societal transformation (Engeström, 1999; Sannino and Engeström, 2018). The activity approach is similar to the “curriculum as a process” approach (Fraser and Bosanquet, 2006; Knight, 2001; Stenhouse, 1975) and to “curriculum as complicated conversation” (Pinar, 2004), where the complexity of curriculum making is present. The object of a collective activity includes multiple alternative goals and actions that are turned into outcomes. The object is not stable, because

after the intermediate goal is reached, it escapes like the horizon does, and new goals and actions need to be negotiated and reconstructed. However, in curriculum development projects, often led by people without educational backgrounds (Lindén et al., 2017) or without training as leaders (Knight, 2001), the short-term goals, actions and technological solutions may be emphasized, leading toward “curriculum as product” or “control over contents” approaches (cf. Fraser and Bosanquet, 2006; Grundy, 1987). These become more visible when elaborating the tools, instruments and mediating artifacts in the curriculum making.

Tools in curriculum making

In the activity system, the tools can be either material or conceptual artifacts. In every activity system, actors use already existing tools but also create new tools with which to “engage, enact and pursue the object of their activity” (Foot, 2014: 336). Tools employed in an activity system reveal something of the actor’s understanding of the object of activity, but they also reflect the cultural-historical context.

Foot (2014) characterizes tools of different kinds with the help of Wartofsky’s (1979) three-tiered hierarchy of tools. The primary tools are quite simple, for example, a protocol for what curriculum should include. Ralph Tyler’s (1949) principles in curriculum design have had a major influence on curriculum making from primary to tertiary-level education (Flinders and Thornton, 2004), and these could be characterized as primary tools. The principles include defining the “goals,” “contents,” “methods” and “assessment,” which can be found as boxes to be filled in, in electronic curriculum systems around the world, and which direct curriculum thinking toward the “curriculum as product” approach (Grundy, 1987).

The secondary tools are representations of primary tools and mediate how actors employ them. In curriculum making, they may be, for example, models or explanatory frameworks. In higher education, the widely used model of constructive alignment by John Biggs and Catherine Tang (2011) could be characterized as such. Even though this model reflects Tylerian elements (Lindén et al., 2017), the emphasis here is in the shift from a teacher- and teaching-focused approach to a student- and learning-centered approach (Bovill and Woolmer, 2019). For academics writing curriculum texts, this means that instead of a list of contents to be taught, teachers should express what the intended learning outcomes are and what a student is expected to learn and achieve during the course. The language forms a tool, a repertoire with which to talk about the object of the activity, and it constructs the reality we are living. The role of language is different in the social sciences and natural sciences, and the conceptual world in curriculum making is different for academics, professional support staff, managers and politicians. In our study, one professor characterized this in the following way:

Some people talked about how we should only use a lot of verbs, you know, they kind of talked down what the whole thing really should be about, but I still can’t quite figure it out myself. Either it is such a big linguistic or mental twist that it just takes time to understand it, or then again, maybe I was just too exhausted to perceive anything.

Source: Annala and Mäkinen, 2016: 13.

Tertiary tools are abstractions, for example epistemological paradigms, that influence the overall direction of the activity system. They may be connected to ideologies and identities and are needed to understand the activity system (Engeström, 1990: 174). This was visible in the previous citation, expressing a need for an explanation and motivation behind the practical actions. Following this need, Fig. 2 was used as a tertiary tool in the university in question, to put on the table the different ideologies and aims and to identify and share what the primary object of activity in their curriculum making was.

Curriculum theorists are most often interested in the tertiary tools, that is, what the ideologies and driving forces are behind curriculum initiatives. For example, the roots of Tyler’s (1949) and Biggs and Tang’s (2011) approaches can be traced to Bobbit (1972/1918), who applied Taylor’s (2003/1911) scientific management in factory production to educational management and planning. At that time, one hundred years ago, curriculum was seen as a way to impact people through education and to respond to the challenges of society. This view is surprisingly similar to the views today in economics-led ideologies and, for example, in the OECD and EU initiatives to boost the economy through higher education and competences relevant to industry (Lindén et al., 2017).

As the more traditional curriculum models rely on educational research, the recent curriculum instruments, such as microcredentials or curriculum mapping, do not have similar roots; instead, “pedagogical jargon” is seen as a barrier (Rawle et al., 2017). These instruments reflect technological and commercial interests (Willis et al., 2016) and are most often used in the natural sciences, especially in engineering and medicine (Rawle et al., 2017). Examples of micro-modules can be found, for example, in the ECIU university network, an EU-funded initiative that “creates a groundbreaking and innovative educational model on a European scale” (ECUI, 2020). Even though marketed as improving educational quality, instead of supporting complex learning, the emphasis is on control and standardization (Wang, 2015) and on observable skills (Carey and Stefaniak, 2018). For example, the technical tools around microcredentials, also known as digital badges, are depicted as a student-centered, working-life-relevant, authentic and democratic way of offering university studies as a new ecosystem (Willis et al., 2016). These tools are described as being in “the intersection of education and motivation, business and data, and badge culture and technology,” and they “stand at the forefront of current credentialing systems” (Willis et al., 2016: 31). As such, they feature universalization, advancement in technology and an emphasis on industry-aligned learning outcomes (cf. Krause, 2020).

Tools of this kind are presented as though they were separate from the other components in the activity system. If academics tune up only their own courses with a focus on the controllable process, the consequences in the system might be unexpected. Besides producing a lack of curriculum coherence and a patchy growth of student expertise, it also changes the role of the university institution. Digital badges are characterized as a new currency of educational power, as they challenge higher educational “institutions privileging exclusivity of education, credentials, and evidence of learning” (Willis et al., 2016: 24). Educational technology companies are involved as stakeholders. This suggests that marketized curriculum space affects not only the curriculum and nature of learning in higher education but also aims to shake the credibility of the university institution (see also Barnett, 2000; Cliff et al., 2020; Krause, 2020).

Rules in curriculum making

According to Sannino and Engeström (2018: 45), “rules refer to the explicit and implicit regulations, norms, conventions and standards that constrain actions within the activity system.” Rules in curriculum making have their formal basis in regulations and standards that originated from educational policy, although higher education has more autonomy compared to other educational levels. As already described in discussing Krause’s (2020) three “vectors of change,” the economic and labor market forces have a growing impact on higher education curriculum from the outside, pushed by the policy requirement to strengthen the university–society relationship (see also Karseth and Solbrekke, 2016; Yates et al., 2017). Also, Priestley (2011) has identified three features in curriculum policy: the growing importance of national qualification frameworks, the shift (or return) to the emphasis on learning outcomes and a move from a subject and disciplinary emphasis toward a more generic curriculum. Yet cultures and histories in the higher education institutions shape the norms and conventions, resulting in the ways in which the rules are interpreted and enacted.

When subjects perceive tools as requirements or demands by those with power, instead of being useful for a subject to engage in the object of activity, tools may be employed as rules (Engeström, 1990: 90; Foot, 2014). As an example, curriculum mapping represents a tool by which to think of how to ensure that certain topics, skills and contents are included in curricula. Curriculum mapping focuses on student learning and encourages a communicative culture among teachers, as they need to collaborate (Rawle et al., 2017; Wang, 2015). In curriculum mapping, special attention is given to student employability and generic/transversal skills. Even though curriculum researchers have underlined the fact that generic skills cannot be isolated from knowledge (e.g. Young, 2011), it is increasingly required to map those skills separately in curriculum making. Online curriculum maps implemented as matrices or forms to be filled out may constrain the curriculum offerings to keep them on track and under control, primarily to serve the work-readiness of students (Wang, 2015). The instrumental way of using tools as rules does not necessarily engage academics who see the object of the activity more broadly. This is visible in the following professor’s comment:

We were given such instructions or restrictions that did not improve the work here. Rather, we were required to struggle against those to prevent or alleviate them so that we could have a territory where we could work reasonably.

Source: Annala et al., 2021.

Another example of rules in curriculum making is how the intended learning outcomes should be expressed in a written text. In Finland, there were guidelines suggesting that the verb “understand” was not allowed, as it was too ambiguous to be evaluated as a learning outcome (see also Biggs and Tang, 2011; Cedefop, 2017). However, some academics disagreed with this notion, as “understanding” was strongly related to complex learning in higher education, for example in the social sciences. This was also our motive for studying the “competence” language in EU policy guidelines in the translations from English to Finnish and studying how academics themselves understood the different concepts in their contexts. What we found was that there is a linguistic inconsistency between different concepts and translations (Mäkinen and Annala, 2010b). Because of this, it was important to see how academics as actors had their own negotiations of meaning: what does a certain concept mean in our context and in our language, and how do we interpret those in our curriculum practice, in our higher education?

We summarized our findings with two paradigms: linear competence and dynamic competency (Mäkinen and Annala, 2010b, 2012). The linear competence paradigm focuses on standardized learning objectives and their assessment. It is manifested in the mainstream guidelines, tools and rules for curriculum making. Dynamic competency relates to student potential and unforeseen learning processes. It is specific to university education, if we see the university as a site of the highest knowledge. In curriculum making, both paradigms are possible and needed, with different emphases in different disciplinary areas and in different phases of studies. Following this, the actors in curriculum making can define some but not all of the specific learning outcomes in detail if we expect our graduates to be future makers, to use their potential and find solutions to the problems the actors themselves (i.e., professors) have not yet been able to solve. Future graduates should know more than the professors of today, which requires a move toward curriculum as empowerment (cf. Annala et al., 2016). Based on our work, our notion is that if competence-based language and models are reflected along with the broader goals and ideas of the university, and if they negotiate a shared meaning between the members of academic community, the tools and rules in curriculum making start to make sense for academics.

The rules reveal how the object of activity is interpreted. People, faculties or institutions follow the rules differently, as curriculum making offers space for interpretations and sensemaking (Annala and Mäkinen, 2016; Sannino and Engeström, 2018). The previous examples concern practical and visible rules in curriculum making, but there are also hidden norms and conventions concerning curriculum making as a part of academic work, including the power relations in the academic community. The rules include some background assumptions about the right and the wrong way of acting, and it is important to ask who wrote the rules and why they should be accepted to govern academics' way of acting (cf. Taylor, 2009). The relations between the subject and community are mediated through the rules that regulate subjects' actions toward an object and relations with other participants (Foot, 2014; Engeström, 1987). This led us to explore the division of labor in the system and academics' roles there.

Division of labor in curriculum making

With regard to the activity system, the question of the division of labor in making curriculum was analyzed earlier as the internal relationships in higher education between academics, professional staff, and leaders, such as the unit chairs responsible for curriculum (Dracup et al., 2020; Cliff et al., 2020). The division of labor was also examined to include the external stakeholders, such as decision makers outside the unit, those in the private sector, NGOs and government (Alexander and Hjortso, 2019). The division of labor concerns the horizontal division of tasks, understood as what is being done by whom toward the object, and the vertical division of power and status, including power, positions, access to resources and rewards (Sannino and Engeström, 2018: 45). Next, I will look at the horizontal division of labor, in the light of the case studies of Kate O'Connor (2020) in the Australian context, and then at the vertical division of labor from the Finnish perspective (Annala et al., 2020). These studies do not reflect the division of labor as a purely internal or external question but contribute to exploring the inner contradictions in the activity system and its relation to the object of activity.

Kate O'Connor's (2020) study concerns the relationship between constructivism, knowledge and curriculum, but it simultaneously points out the role of academics in curriculum making with regard to online modules. In those cases, the role of the academics was to produce subject content and knowledge, but after that, to leave the teaching to external tutors or casual teachers or to students studying collaboratively by themselves online. The ownership and implementation of curriculum moved from academics to online experts and casual teachers, appearing as a cost-effective way to implement curriculum. The core concern was whether knowledge about teaching practice could be isolated from the knowledge about the content taught. The online modules were put forward as student-centered and constructivist ways of supporting active learning, but the implementation positioned curriculum knowledge as fixed and stable rather than as complex and negotiated with different cohorts of students (O'Connor, 2020). The role of academics with a deep understanding of the topic was not acknowledged; instead, the lecturers were blamed for overloading their subjects with too complex an approach. The leaders asked the lecturers to reduce the content, despite the nature of the subject, to be fixed and stable long term, in order not to waste time and in order to fit the new online formula.

This is an example of the consequences of unbundling the curriculum making from the teaching activities (Cliff et al., 2020; Tucker and Neely, 2010). Ryan et al., (2017) see that a strong division of labor in academia is a risk to university teaching quality and reputation while being the university's main source of income. The formal pressures on core academic staff to increase their research performance and ignore teaching threatens the "idea of a university" as a "social institution dedicated to both the creation and dissemination of knowledge in the public interest" (Ryan et al., 2017: 69). Simultaneously, as some stakeholders emphasize the cost-effectiveness of curriculum, others aim to keep its profile distinct from other educational institutions, emphasizing that teaching and research are closely intertwined in curriculum making (Annala and Mäkinen, 2011; Visser-Winjeveen et al., 2010). In our study, one professor described this as follows:

Vocational, professional and scientific goals are contradictory. It should not be denied. We should defend the status of scientific approach and research. But most of all, we should think how we could take advantage of these tensions pedagogically.

Source: Annala and Mäkinen, 2011: 13.

The vertical division of labor with respect to academics' power, positions and access to resources and rewards became visible in our study on agency and structure in curriculum making processes (Annala et al., 2020). We applied Bourdieu's field theory and looked at curriculum making as a specific field of struggle. When looking at the division of labor at the department level, the diversity of internal participants in curriculum making, including students, academic developers, casual teachers and doctoral researchers, was not always seen as a resource but was sometimes seen as a threat to the professoriate (Annala et al., 2020). This was especially the case when curriculum and teaching were seen as separate from research. Instead, the enhancement of the research-teaching nexus and shared conceptual tools had an important role in engaging academics in curriculum making and in regarding it as a meaningful part of academic work. This implies that curriculum making would benefit from being framed more holistically, not as instrumental and short-term action and not as administration and teaching-related activity but as teaching and research-related activity.

Yet academics' narratives of curriculum making demonstrated power relations when there appeared features of a game with winners, losers and survivors along with stable narratives featuring development-orientation, autonomy and opposition (Annala et al., 2020). Curriculum making had hidden rules and raised questions of who had agency and power and how to

have them in curriculum making. In a university-wide curriculum change, the status of different disciplines played a role. For some, the strategic guidelines and structural frameworks created an activity system with rules and tools that improved their position in the field, whereas for some other disciplinary fields, the consequences were the opposite. Ylijoki and Ursin (2013) also state that specific areas in the natural sciences, technology and medicine are often so valued by the university and society that they can shape the rules in academic practice. The question is whether these disciplinary fields place more value on tools of a certain type in curriculum making and how this affects curriculum making more broadly within different communities, institutions and universities (see also Barnett, 2000).

A vertical division of labor, emerging as broader power structures, seems rather influential in curriculum making in academia. Power relations can promote a collective capacity to innovate and create new practices, but they may also restrict collaboration and decision-making in the activity system (Haapasaari, 2020). Following the premises of activity theory, tensions and contradictions here could be transformed toward innovative ideas and solutions, through “incremental developmental steps, radical changes in tools, processes and practices, or system level changes that transform the entire course of action” (Haapasaari, 2020: 4). These all require collaboration in the academic communities as well as analysis of their curriculum making practices.

Community in curriculum making

A community of significant others consists of individuals and subgroups who share with the subject an interest in and involvement with the same object (Sannino and Engeström, 2018: 45). When thinking of the activity system, relations between the subject and the community are mediated through the rules that regulate subjects’ actions toward an object, their relations with other participants and the division of labor (Engeström, 1987). As such, features of the community are strongly linked to the earlier sections of this paper. When looking at the activity system from the perspective of academics, the way curriculum making is implemented in the community is important.

Professional staff and academic developers are often the mediators of the rules between the policy guidelines, management and academics. Handal et al. (2014) explored academic developers’ experiences between internal and external pressures in Norway. They analyzed the actions and arguments of academic developers in curriculum making when implementing the National Qualification Framework (NQF), part of the Bologna process. The academic developers struggled between compliance and resistance, as there were tensions between decisions and guidelines coming from outside, from the Ministry and from the complex nature of higher education where they acted. They had better knowledge that the directions for formulating learning outcomes did not fit all the disciplinary fields similarly, but the Ministry had power as a decision-maker superior to the universities. Academic developers had professional accountability to induct academics into practices and procedures defined by politicians who did not have better knowledge of the higher education curriculum, but simultaneously, the developers had the professional responsibility to facilitate more academically and theoretically driven pedagogical practices (Handal et al., 2014). Similarly to the notions of O’Connor (2020), Handal et al. (2014) state that the core concern is that knowledge about teaching practice cannot be isolated from the knowledge about the content taught.

Handal et al.’s (2014) study revealed that not only curriculum but academics as well are considered as objects of activity, to be inducted into certain ideas and practices. This signals that from the perspective of policy, academics are either reluctant to join curriculum making processes or they may approach them in an unfavorable way, with tools or rules that do not fit the dominant agenda. This represents “resource power,” described by Haapasaari (2020) as one layer of power in the activity system, that is, power over others and the control of resources. Another layer of power described by Haapasaari (2020) is “process power”, which refers to organizational decision-making processes, and a third layer is “meaning power”, which manifests in dominant perceptions in an organization. Following all these layers, close attention to all the elements in the activity system is needed. What is the community of significant others who are involved in curriculum making? Do the academics, casual teachers and professional developers have ownership in the curriculum making and implementation? What is the role of external stakeholders? And how and where are the final decisions made? Academic pedagogical leadership in the curriculum process in communities was a recurrent topic that emerged in our studies, exemplified in the following:

There should’ve been someone kind of coordinating the process [–] there we had this fine theoretical knowledge and a vision, a concept, the idea of what we were trying to do. So that one doesn’t just go right ahead to the implementation, and start talking about courses one wants to get rid of, or how the basic courses should be changed, instead first we should have had this phase with absolutely no comments allowed regarding any of the courses. We should have talked about what this or that means, what are the premises we can commit ourselves to.

Source: Annala and Mäkinen, 2016: 11

This notion brings to the fore the question of whether academics themselves are subjects in curriculum making and whether they have genuine access to the negotiation of meanings of the object of activity in the academic community—do they have meaning power (cf. Haapasaari, 2020)? Results from our study indicate that in many cases, the curriculum change deeply touched the academics’ expertise areas, pedagogical philosophies and research fields, thereby resulting in commitment to the curriculum making process (Annala et al., 2021; see also Priestley et al., 2012). The academics’ engagement in curriculum making was also connected to the changes in structure; for example, academics’ experience was that university-wide curriculum change favored more hierarchical

and hard qualities than dialogical, collegial and pedagogical. The hierarchical qualities are an example of Louvel's (2013) characterization of curriculum making as an "engineering type" of activity where a plan is followed to meet the expected optimal solution.

As an alternative, Louvel (2013) characterizes curriculum making as a creative "bricolage type" of activity. She refers to how individuals and groups create something new by interpreting the rules creatively, using the existing rules as a resource but stretching them to fit their reality. It is clear that academics do not simply cope as passive receptacles of suggested changes in curriculum making; instead, they adopt and reject, negotiate and contest (Brøgger, 2014). Similarly, we found that the institutional, community and individual layers enabled and impeded implementation of academics' agency in curriculum making (Annala et al., 2021). The direct work community played an especially significant role in engagement in curriculum making, despite how large the change or reform was. The role of community in the activity system of curriculum making could be characterized as follows: "When people are provided with opportunities, forums and tools for participating, they take agentive actions and initiate innovative solutions to collaboratively develop joint activity" (Haapasaari, 2020). If there is room for collaboration and a capacity to work with others, it is also possible to expand the object of activity.

Conclusion

In this article, the aim was to analyze curriculum making in higher education, with the help of concepts from the activity theory, with specific focus on curriculum as an object of activity. The emerged contradictions, often dichotomic, reveal that not only do universities, disciplinary fields, policy-makers, students and other stakeholders see the object of activity differently, but academics also do not have a shared view. The tensions between different disciplinary fields are present, especially when the rules that are aligned with the histories and cultures of some fields are pushed by the education policy to other fields, faculties and institutions of different types. The three vectors of change described by Krause (2020) appeared clearly in the analysis of curriculum making.

Taking fully into account the various perspectives, the contradictions and dynamics would require applying third-generation activity theory (Engeström, 2001), where two or more activity systems are brought together through a common object. Doing so would contribute to an analysis of how different actors are positioned in the activity systems and how they see the tools, rules and other components. Yet there is a risk that we may focus exclusively on the subjects and actors (Engeström et al., 2003), while the key question remains: is there a common object of activity, and how it is understood? Thus, it is necessary to put on the table the object of activity, what this is all about. My key argument is that a necessary glue in curriculum making is to focus on the object of activity (cf. Engeström et al., 2003). This is also the message from activity theoretical thinking: It is important to take objects of activity seriously (Blackler, 2009; Engeström et al., 2003).

It is also important to pay attention to tools, as they may simultaneously have enabling and constraining elements (Kuutti, 1996), that is, how they are used or could be used by academics and whether they fit all the disciplinary fields similarly. What is problematic here is that when curriculum scholars have focused on tertiary tools, i.e. ideological critiques and philosophical questions, they have offered little if any support for practical tools in curriculum making (see also Priestley, 2011; Young, 2013). Then again, academics, managers and politicians who are unfamiliar with educational sciences easily prioritize questions at hand in curriculum making without a need of or interest in historical, political or societal analysis (Lindén et al., 2017; Young, 2013). The primary and secondary tools are brought to the fore as they make the curriculum process concrete, effective and manageable. The cultural-historical background of curriculum initiatives, especially if they cross national and disciplinary borders, needs transparency. For this reason, I argue that tertiary tools are strongly needed in curriculum making, as they contribute to understanding the rules, motives and ideologies behind the curriculum protocols and models, and they help academics and other stakeholders evaluate the possible outcomes and consequences of the chosen actions in curriculum making, not only locally but globally.

One of the key contradictions in the activity system is the desired outcome and the use value and exchange value of the object (Engeström, 1999). The superior quality of teaching and learning was suggested as one possible outcome in curriculum making. Yet the analysis showed that unintended outcomes and consequences may appear for academics, university education and university institution if some stakeholders dominate in curriculum making. Following this, a fundamental question is what is of value in the higher education curriculum and is it possible to find interconnected views that bridge the different interests. Paul Ashwin (2020) summarizes this issue as follows:

The educational purpose of a university education is not to prepare someone for their role in the future workforce. Rather, the educational purpose of a higher education is to bring students into a transformational relationship to knowledge that changes their sense of who they are and what they can do in the world. This undoubtedly prepares them to make a contribution to society, including through their contribution to the labour market but this is a by-product of the central educational purpose of a higher education rather than its driving force.

Source: Ashwin, 2020: 3

Those who understand curriculum making more broadly are needed in the academic communities and as decision makers in curriculum changes; they may be educational developers or academics themselves if they are given access to be Subjects who define the rules and tools that make sense for academic purposes. When object and motive are reconceptualized, a radically wider horizon opens up (Engeström et al., 2003). This could thus enable the academic community to see curriculum making possibilities as a process to empower and to make changes to society, not just to follow what is there but to see the horizon of possibility.

Acknowledgments

I would like to express my deep gratitude to my fellow researchers, Professor Marita Mäkinen and university lecturer Jyri Lindén, for partnership in research on higher education curriculum during the last decade. I am also grateful to Professor Annalisa Sannino for her comments on this article.

Introduction

No curriculum is value-free. Decisions relating to what, and how, young children should learn are open to multiple influences and interpretations, and have long been the subject of international debate. This is because curriculum decision-making is implicated in the political, cultural and economic contexts within which it is situated. It is shaped by particular perspectives about childhood, learning, what counts as knowledge and valued ways of coming to know and understand. Ultimately, then, curriculum acts as a mirror that reflects political and societal values regarding the purpose of early childhood education (ECE) and ways young children are viewed in society.

With these points in mind, our planning and development of this chapter was informed by the following questions: Who are the curriculum makers in ECE? How does curriculum making reflect views/images of children? How does curriculum making reflect common social and political perspectives/views that a main purpose of ECE is school readiness? What, and whose, knowledge, underpins curriculum making? And in what ways might curriculum produce strong inquirers or compliant learners? Drawing upon our research, we show the potential of approaches to ECE in which children's interests are the focus of curriculum making decisions.

Children's interests have long been recognized as contributing to curriculum making in early childhood, but suffered from narrow interpretations. By the end of the first section of this chapter we have problematized two entrenched contributions to decisions about foci of interests-based curriculum making in early childhood and offered an alternate proposal. Our proposal is built from views of children as capable and motivated learners whose diverse life experiences can drive curriculum and therefore position children as leading curriculum making in ECE.

In section two we present three theoretical framings for children's interests: developmental psychology, sociocultural theory and post-humanism. We argue that each framing illuminates interests for curriculum making differently. In section three we develop our proposal about interests and capabilities to make a case for a dynamic approach to curriculum making that is driven by deep analysis and authentic interpretations of children's interests and play choices. We draw on our research to introduce and exemplify concepts and approaches that emphasize the ways that inquiry and identity are central to children's interests.

The final section attempts to resolve dilemmas the first section raised about curriculum making focused on narrow ideas about outcomes and school readiness. We address these concerns through the alternate ideas about curriculum making based on interests and selected ideas of Bruner (1960, 1996). We show how interests-based outcomes inspire children's learning and promote this as an alternative form of "readiness" in which children make sense of the world through curriculum making that has contextual meaning and relevance. Throughout the chapter we offer examples of children from our research projects that exemplify the curriculum making potential of children's interests.

Section one: critiquing an entrenched coalition

International research and debate about curriculum in ECE highlight two key drivers that exert a powerful influence upon curriculum making in many contemporary contexts (see, for example Wood and Hedges, 2016). First, developmental psychology and associated child development theories have had an enduring influence upon the construction of many national curriculum frameworks for ECE. These frameworks are informed by Piagetian notions of development that establish linear expectations and progressive sequences relating to developmental milestones by which to understand and assess children's learning and achievements. Second, the political appeal of investing in the early years for future economic prosperity has led to including approaches that prioritize academic outcomes. Such approaches foreground ECE as a site for school readiness in order to generate a productive workforce for the future.

Taken together, the coalition of child development theory and political ideology has created dominant framings of curriculum in which educational success and progression are measured in terms of decontextualized academic achievement, often with a focus on early literacy and mathematics. Driven by this ideology, the Organization for Economic Cooperation and Development's (OECD) controversial cross-national assessment of five-year olds, the International Early Learning and Child Well-being Study (IELS), is indicative of the global preoccupation with instrumental measures of children's progress. The priorities that drive the IELS have been subject to widespread criticism by early childhood scholars and practitioners (see, for example, Moss and Urban, 2020) and are likewise enacted in many national policies that construct reductive approaches to young children's progress and school readiness. Wood's (2020) critical discourse analysis of the Early Years Foundation Stage (EYFS) (DfE, 2017) curriculum in England reveals how the EYFS exemplifies a global preoccupation with linear notions of progress and school readiness.

This framing of curriculum is informed by a standardized conceptualization of knowledge in which predetermined learning outcomes are assumed to have universal relevance for all children (Chesworth, 2019). Assumptions of progress and readiness have played a powerful role in shaping dominant framings of ECE curriculum and have generated a simplified construction of knowledge that erases the social, cultural and historical contexts within which young children live and learn. The assessment of children in relation to universally imposed norms constructs notions of the "deficit" child, family and community by which children who do not align with normative learning outcomes are positioned as somehow lacking or problematic (Burman, 2008). Hence, curriculum making in ECE has often been viewed as a teacher-directed social and academic intervention, designed to redress assumed social and economic disparities, and enhance children's readiness for the formality of school-based instruction with an eye on future economic productivity.

Thus, an outcomes-driven agenda exerts a powerful influence upon what knowledge and ways of knowing are deemed to have value and validity in curriculum making. In this standardized enactment of curriculum, young children are ascribed a passive role in which they are positioned as recipients of knowledge. Such an approach runs counter to the overarching tenet of this chapter: we argue that curriculum making should start from the premise that all children, no matter their life circumstances, are eager, competent and capable learners. Children's lives are situated within specific cultural contexts. Normative outcomes mask the complexity and diversity of children's learning and development. "Treating European American middle-class people and their communities as the "norm" is misleading and undermines understanding of both the generalities and the specifics in human development world-wide" (Rogoff et al., 2018, p. 4), a point we exemplify shortly in refuting deficit accusations and instead highlighting children's capabilities as learners.

A credit-based approach to children's learning and curriculum provision requires that teachers pay attention to diverse knowledge and ways of knowing that are mediated by children's active participation in the everyday activities of their families and communities. Rogoff, Correa-Chávez and Dexter (2015) frame these everyday activities as "cultural repertoires" which shift the focus of development from an individual trajectory toward recognition that learning takes place in the context of social interactions and relationships. From the many experiences children participate in, some connect with and/or spark their curiosity more than others. These become the kinds of sustained interests this chapter champions. This perspective recognizes that young children and their families have the potential to play an active role in curriculum making. It places value upon contextually situated knowledge and diverse ways of knowing. In this way, the goal of curriculum making shifts from decontextualized measures of academic performance toward enabling children to move toward learning grounded in deeper understanding from and in meaningful contexts.

Furthermore, standardized curriculum frameworks can lead to a technicist framing of interests in which teachers' interpretations are informed by predetermined learning outcomes rather than the everyday lived experiences of children and families (Chesworth, 2016, 2019). For example, a child may be interested in a book about going fishing with a grandparent, and while reading it be eager to share their knowledge and experience with a teacher, who instead diverts the child's attention to the literacy features of the book aware of the accountability measures s/he will be subject to. As such, we suggest that curriculum making informed by children's interests requires a stronger conceptual framing that addresses a middle ground between child-initiated play and teacher-led learning, foregrounds children's perspectives in order to avoid narrow, tokenistic or instrumental connections between interests and curriculum, and requires a rethinking of what constitutes outcomes and school readiness.

In this section we have problematized approaches to curriculum making that are driven by linear interpretations of child development, standardized learning outcomes and deficit notions of diversity. We have presented a case for curriculum making that recognizes children as competent and capable learners, and that is responsive to children's interests derived from diverse experiences in families and communities. In the section that follows we consider how a focus upon children's interests can inform curriculum making from three theoretical perspectives.

Section two: theoretical framings of children's interests

Play has been established, both historically and presently, as a strong foundation for children's development and learning (see, for example, Brooker et al., 2014). The rhetoric of building a curriculum upon children's play choices and interests is also well established within ECE curriculum documents and practice, if somewhat unproblematized (Wood, 2014) or researched until recently. Children are motivated to learn through connecting new experiences to what they know and are interested in. Interests, therefore, afford possibilities for meaningful curriculum making that has relevance for children's diverse lived experiences. Interests offer a potential means for "children and teachers to spontaneously inquire into and explore intuitive ideas, and the content relating

to these, in highly participative and interpretive ways" (Hedges, 2015, p. 303) rather than curriculum making being prescribed by outcomes to which teachers are held accountable.

However, notions of what constitutes "interest" are not universal. These notions are shaped by different theoretical and ideological perspectives about children, childhood, learning and pedagogy that we explain next.

Justification for the longstanding interpretations of children's interests within many curricular frameworks as emphasizing upon children's individual engagement with materials or activities within ECE play environments have derived from developmental and educational psychology. Related research offered children choices of toys or play equipment in experimental studies and deemed the activity selected as the interest. However, an activity-based framing of interest first implies a surface or low-level interpretation that has a tendency to underestimate the depth and complexity of children's thinking, reasoning and motivations to learn that are represented in that choice of activity. Second, this framing does not take account of cultural repertoires, whereby many settings continue to rely on Western ideals of play equipment and neglect considerations of equity and diversity in the choices made available to children. Third, adult roles were viewed as "hands-off", with safety and supervision overriding foci rather than offering input into children's play and subsequently, knowledge development of interest to children that fostered ongoing curiosity, knowledge building and thinking.

From a sociocultural perspective, curriculum-making can be informed by participatory approaches in which young children's play-based learning is understood to be mediated by interaction in social and cultural contexts (Rogoff, 2003). This perspective calls for children's interests to be interpreted in relation to their participation in family and community activities. Viewed as such, children's interests can enable teachers to notice, understand and respond to the cultural repertoires (Rogoff et al., 2015) that inform children's construction of identity and dispositions to learn in diverse sociocultural contexts. In this way, building a curriculum in response to children's interests offers potential for children to apply and transform knowledge, leading to deeper understanding in meaningful contexts.

Supporting this alternative position, we have contributed to a recent and significant body of international research that highlights the benefits of using children's interests developed in their families and cultures as a basis for curriculum-making (Chesworth, 2016; Hedges et al., 2011). In this chapter we next focus upon studies from this body of work that have applied and extended the concept of funds of knowledge (González et al., 2005) to illuminate approaches to curriculum that value, connect with and build upon the interests that children amass from their participation in home and community activities. Informed by sociocultural theory, the notion of funds of knowledge highlights the richness of experiences arising from children's participation in household and community activities. Moll et al. (1992) have proposed that all families, whatever their economic, social and cultural circumstances, have "ample cultural and cognitive resources" (p. 134) arising from funds of knowledge associated with everyday household functioning, development, relationships and wellbeing. The principles that inform a funds of knowledge approach to understanding children's interests have much in common with Bruner's beliefs regarding the connections between culture and curriculum that we discuss later.

From a sociocultural perspective, children's interests are motivated by a desire to participate in, and make meaning of, the cultural lives of their families and communities. Funds of knowledge-based interests arise from children's active participation in household practices, including domestic tasks, holidays and community experiences as well as through the influence of family members' occupations and leisure activities (Hedges et al., 2011). Funds of knowledge-based interests can also be influenced by less tangible aspects of home and community activity including family and cultural values, beliefs and languages (Hedges et al., 2011). For example, a child might develop a deep interest in growth, change and caring for plants as a result of funds of knowledge amassed from helping a parent or grandparent in the garden. This could generate appreciation for sustainable gardening practices and respect for wildlife and ecology. Likewise, children might develop interests relating to their participation in household activities relating to food preparation, baking or contributing to the care of younger siblings. Funds of knowledge-based interests could also develop from participating in religious activities or from observing a parent's engagement in hobbies or sporting activities. Locating interests within the multiple sources that constitute funds of knowledge can consequently inform curriculum making that responds to and sustains the diversity of practices and interactions that constitute young children's everyday lives (Chesworth, 2014).

Contemporary studies have built upon González et al.'s (2005) work to acknowledge a broader spectrum of funds of knowledge that extend beyond children's participation in family activities. Such studies highlight the ways in which funds of knowledge-based interests arise from children's participation in multiple contexts, including their interactions with popular culture (Chesworth, 2016; Hedges 2011; Poole, 2017), and with teachers and peers in ECE settings (Hedges et al., 2011).

Funds of knowledge that are selected as meaningful, that is, are of interest, have recently been termed funds of identity (Esteban-Guitart, 2016; Esteban-Guitart and Moll, 2014) and extended into early childhood education (Hedges, 2021). We see the concept of funds of identity as being particularly helpful in illuminating how children's interests arising from lived experiences contribute to their sense of themselves as members of social and cultural communities. Viewed through a funds of knowledge and/or funds of identity lens, children's interests afford potentially meaningful opportunities for curriculum making that values, connects with, and extends children's diverse knowledge and ways of knowing.

A recent theoretical framing we see has potential with regard to children's interests is post-humanism. Many Indigenous Peoples have long understood the world as an entanglement of human and non-human elements (Pacini-Ketchabaw and Taylor, 2015) and recent years have seen interest in bringing these ideas to Western educational theory. For example, New Materialism and the broader ontology of posthumanism within which it resides, locate learning within vibrant ecologies in which humans and nonhumans are always intra-acting, always in relation with one another (Pacini-Ketchabaw et al., 2017).

A post-human framing can inform further work to be undertaken to understand how interests may emerge from children's engagement with aspects of their everyday worlds that do not sit within a classification of social or cultural experiences. This position affords possibilities to adopt a broader lens to explore children's interests (Chesworth, 2019) by extending interpretations beyond social and cultural factors in order to explore a wider range of "causal factors for understanding what is going on in an educational encounter" (Murris, 2016, p. 91). For example, a post-human perspective can enable teachers to move toward deeper interpretations of children's interests that arise from their relations with places, animals, insects and other non-human things to which children are often deeply attached.

We clarify that while a post-human lens offers potential for new insights into interests, such a reading does not reject the importance of children's participation in sociocultural practices; rather, it blurs the boundaries between social, cultural and nonhuman factors which interweave within and beyond children's everyday experiences. Locating young children's interests within their affective and practical relations with human and more than human aspects of their everyday lives recognizes that learning is dynamic, responsive and situated. Viewed as such, children's interests are constructed through connections, and are open to new connections that lead to new knowledge and understanding. A post-human understanding of interests complements sociocultural positions that foreground children "being part of the world" (Haraway, 2020) and therefore central to curriculum making. As such, post-humanism affords possibilities to build upon, not replace, participatory perspectives of interest (Chesworth, 2019). However, there is to date no empirical work that identifies and evaluates the ways in which this position can inform interests-based approaches to curriculum-making in ECE.

Of these framings, our research on children's interests has been situated in sociocultural theory. We have identified play, funds of knowledge, inquiry and identity as significant in interpretations of interests that can inform curriculum making. We have offered examples of play that draws on funds of knowledge in this section. Such curriculum is authentic to children because it respects their lives and experiences. It builds personal, academic and societal knowledge in the context of children's interests-motivated participation in play-based activities that have deep representational possibilities and meaning for children. We now go on to explore ideas from our research of children's interests framed as inquiry and identity development, and illustrate their power for curriculum making.

Section 3: children's interests as inquiry and identity development

This section introduces a dynamic approach to curriculum making that is informed by interpretations of children's interests as centered on meaningful inquiry and identity development. In contrast to constructions of curriculum that position children as passive recipients of knowledge, a dynamic curriculum recognizes that children and teachers play an active role in curriculum making together in both planned and spontaneous ways. Such an approach is driven by respect for children's capabilities; informed by sociocultural theory, we locate these capabilities within children's relationships, local contexts and cultures. These understandings of children and culture lay the foundations for curriculum making that is respectful of, and responsive to, children's diverse lives and experiences. Such an approach requires teachers to know children and their families well enough to identify and respond to the funds of knowledge-based interests and "real questions" (Hedges and Cooper, 2016) that children are investigating through their play and inquiries. This highlights the central role of relational pedagogy: respectful dialog and responsive relationships with children, parents and caregivers in order to inform in-depth interpretations of, and responses to, the individual and collective interests that children enact in early childhood settings.

Children's play choices in early childhood settings represent and mediate their interests and intentions (Göncü, 1987). As such, self-initiated play-based learning affords possibilities for children to explore and extend personal and shared interests with peers and teachers. For example, Chesworth's (2014) research indicated that children's play choices were driven by a motivation to connect with, and deepen their understanding of, the people, practices and places that constituted their everyday worlds. As such, play has potential to be a cultural broker (Walker and Nokon, 2007) in which funds of knowledge-based interests connect ECE settings, homes and community contexts, and enable children to making meaning of the different activities that constitute their sociocultural worlds.

Our research exemplifies the possibilities that play affords for children to draw upon familiar adult scripts (Göncü, 1987) that have interest to them, and to imagine themselves into identities that are complex and creative (Holzman, 2010). For example, Ellie and Lily, both five-years old, co-constructed a play narrative in which they prepared for an imaginary party. The children enacted mutual funds of knowledge of baking and birthday celebrations and also drew upon their shared interest in Disney princess movies to introduce a fantasy element to their play. In this episode of play, Ellie and Lily co-ordinated their activity through a complex blending of meanings, in which funds of knowledge arising from diverse sources were interwoven to imagine new scenarios and identities (Chesworth, 2016).

Noticing the funds of knowledge-based interests that children are exploring during play offers important possibilities for teachers to respond to and extend learning in ways that have meaning and relevance for children's learning and identities. This approach offers a framework for a dynamic model of curriculum making that is attuned to the complex meanings and motivations that children bring to their play (Hedges, 2021; Hedges and Cooper, 2016). Furthermore, this approach offers a potential lens to notice the ways in which funds of knowledge-based interests connect with children's identity construction and to value the ways in which individuals create their identities through experiences that have particular interest and meaning for them (Esteban-Guitart and Moll, 2014; Hedges, 2021).

For example, in the case of Ellie and Lily, teachers could draw upon their knowledge of the children to bring greater depth to their interpretations of interest in ways that progress beyond noticing the sources of interest (baking, birthday parties and Disney films) to identifying the “real questions” that the children were exploring in their play. Such questions might, for example, revolve around children’s inquiries into present and future identities, such as: How do my experiences enable me to connect with others? Who am I and what can I do? Who else can I be? In another example, Hunter had immense skills in playing the drums. Analyzing this interest as activity-based only would have missed the deep cultural meaning music played in Hunter’s life. This interest represented his funds of knowledge, and his interest in developing his identity as a member of his family, cultures and communities. In turn, the curriculum experiences teachers developed for him led to him developing an identity as a confident learner and communicator that would stand him in good stead for schooling in ways a focus on academic readiness would not have achieved (Cooper and Hedges, 2014).

Dynamic modes of curriculum making, therefore, afford opportunities to affirm children’s identity construction and to extend learning through open ended, flexible responses that are attuned to children’s authentic questions and intentions. This means that teachers’ in-the-moment pedagogical interactions with children, as well as subsequent planning for future learning experiences, need to be synchronous with children’s interests, motivations and inquiries. In this way knowledge and skills can be brought forth/contribute to children’s learning through the sensitive, relational and conceptual input of teachers. This approach to curriculum making recognizes children’s curiosity and motivation to explore their interests in new contexts. Children actively seek new information that stimulates further inquiry and investigation when the source and context of the curriculum is their interests.

Foregrounding inquiry and identity is indicative of a holistic approach to curriculum making. An inquiry-driven approach to curriculum-making is informed by respect for children’s motivations and capabilities to move toward deeper understandings and apply their learning in new contexts. This mode of curriculum foregrounds the co-construction of meaningful knowledge through a dynamic and collaborative process involving children and adults. In this way, children’s interests and playful explorations are valued while teachers draw upon their deep knowledge of children to mediate new opportunities for children’s knowledge development and critical thinking (Hedges and Cooper, 2018). Moreover, as Peters et al. (2018) argue, a curriculum that foregrounds mutual exploration, challenge and curiosity leads to more complex understandings for children and teachers alike. Children seeing teachers as enthusiastic models of learning further ignites their inquiry and knowledge building.

In summary, a holistic view of curriculum recognizes the interweaving of cognitive and affective aspects of learning and offers an alternative to curricula frameworks that emphasize academic outcomes over affective and emotional domains of learning. This holistic view constitutes a significant shift from the deficit models of curriculum delivery that were outlined and problematized earlier in the chapter. Deeper interpretations of children’s interests as inquiry and identity construction offer rich possibilities for teachers to interact with children in relational ways that create broad, balanced and playful learning experiences that are responsive to children’s diverse experiences and ideas (Hedges and Cooper, 2018). These interpretations also have the potential to incorporate the knowledge valued by society represented in more recognizable ways as academic outcomes, an idea we explore next in our final section connecting culture with learning and knowledge building.

Section 4: “intellectually honest” curriculum making

The conceptualizations of children’s interests presented in this chapter offer ways to interpret and respond to children’s interests with authenticity. This is critical to curriculum making that is cognizant of children’s interests and highlights the vital roles teachers play in co-constructing learning experiences that have meaning and relevance for children.

Teachers notice the activities that children choose, valuable in themselves for play and learning experiences, but when aligned with deeper interpretations of interests as representing funds of knowledge, inquiry and identity development can recognize, respond to, extend and revisit them differently than as mere activities. Extending and revisiting enables children’s knowledge to grow in topics/subjects that are meaningful to them, that they are motivated to learn. However, all play-based activities available represent the explicit and implicit cultural values and priorities of the context they are located in, hence connections between culture and learning are always central to educational possibilities.

The relationship between culture and learning was a career-long focus of Jerome Bruner’s. In his 1960 book on *The process of education* Bruner made a provocative statement that aligns with the central idea in this chapter that children are capable and competent learners.

We begin with the hypothesis that any subject can be taught effectively in some intellectually honest form to any child at any stage of development. It is a bold hypothesis and an essential one in thinking about the nature of the curriculum. No evidence exists to contradict it; considerable evidence is being amassed that supports it (p. 33).

This statement is also powerful for considerations of the conceptual possibilities inherent in children’s interests, possibilities that may have the potential to address considerations of school readiness in more child-focused ways. There are naturally considerations of caveats about the degree to which a subject can be taught related to children’s maturity and life experiences. Perhaps this is partly what Bruner meant by an “intellectually honest form”?

Nevertheless, we have all met a child who, for example, knew more about dinosaurs or sharks than we will ever know. Campbell had a deep interest in all sea creatures, an interest that had been fostered by family fishing expeditions as a source of funds of knowledge. He brought this interest to kindergarten through his choice of playing with plastic animals. A teacher who listened intently to Campbell realized the focus of his interest and initially added to the resources provided (more plastic creatures and books about sea creatures). Campbell's interest sparked further curiosity and a thirst for knowledge. For example, he and a teacher used a tape measure in the playground to measure and demonstrate the length of a whale shark. In these ways early literacy and numeracy prized by many curricular outcomes were incorporated in Campbell's learning, and his knowledge of the "subject" of sea creatures was both intellectually honest and developed over time in increasingly complex and additive ways (Hedges, 2004).

There are then also understandings of the associated processes of children's learning and thinking and curriculum making that Bruner was very clear about, well ahead of his time. His points relate closely to our arguments about children's interests. Bruner outlined the importance of the roles of curiosity, inquiry, perception and intuition in children's learning, and ways that research to that date – over 60 years ago – acknowledged children's capabilities. These we argue form the ways that a subject could be addressed through inquiry in an "intellectually honest form".

Bruner argued that interest in a subject – perhaps a topic of deep interest as exemplified by Campbell's interest in sea creatures – was the motivation for learning. Aligning with Vygotsky's (1986) statement that "direct teaching of concepts is impossible and fruitless" (p. 150) Bruner reasoned that didactic teaching did not enable the "excitement about discovery" (p. 20) nor develop the dispositions of curiosity and inquiry necessary for learning. For Bruner, learning and knowledge building required access to information alongside ongoing opportunities to apply and transform knowledge in new situations while simultaneously evaluating the value of that information. He implied that where children had great motivation and deep interest that related subject information could be taught through participatory and mediated teaching and learning.

For example, when Liz was teaching she noticed that four-year old Faizah regularly brought brushes and water from the painting area and used them to wash the nursery cars and trikes. Subsequent conversations with Faizah and her parents revealed that Faizah's father had recently set up a car valeting business following a long period of unemployment. Careful listening to the family enabled Liz and her colleagues to understand that Faizah's interest was closely connected to her relationship with her father and to the family's collective pride in his new business venture. In response, they introduced additional sponges, cloths and brushes so that Faizah could explore, extend and share her interest with other children. Faizah's interest led to the children and their teachers creating a car wash in the nursery garden that generated further opportunities for learning. For example, Liz encouraged children to predict, observe and talk about the effect of different cleaning materials and solutions (for example, soapy, hot and cold water). On another occasion Faizah brought in a valeting menu from her dad's business and engaged with a teacher to produce an itemized list that presented the washing prices for each of the nursery vehicles. These examples are indicative of Bruner's argument regarding the potential for knowledge building in contexts that have meaning and relevance for children's lives. Bruner's position resonates with Vygotsky's (1987) seminal work in which he argued that the relational connection between concrete experiences and academic concepts underpins and drives the process of learning. Faizah's interest offered a meaningful context in which everyday experiences and academic concepts could connect and lead to deeper mathematical and scientific understanding.

With these critical points, and the associated examples of Campbell and Faizah in mind, we offer Bruner's view of curriculum making: the notion of a spiral curriculum. He stated that:

If one respects the ways of thought of the growing child, if one is courteous enough to translate material into his logical forms and challenging enough to tempt him to advance, it is possible to introduce him at an early age to the ideas and styles that in later life make an educated man. We might ask, as a criterion for any subject taught in primary school, whether, when fully developed, it is worth an adult's knowing, and whether having known it as a child makes a person a better adult. If the answer to both questions is negative or ambiguous, the material is cluttering the curriculum. If the hypothesis with which this section was introduced is true - that any subject can be taught to any child in some honest form - then it should follow that a curriculum ought to be built around the great issues, principles, and values that a society deems worthy of the continual concern of its members.

(Bruner, 1960, p. 52, p. 52).

The idea of great issues, principles and values as the basis for curriculum has resonance with the notion of fundamental inquiry questions as the ideas that underpin children's interests and that drive their learning. Perhaps the example of Campbell shows ways teachers could introduce authentically issues of sustainability and conservation as representing issues, principles and values vital to the world that need ongoing problem-solving and innovative responses. The fundamental inquiry questions might be: How can I understand the world I live in? What do intelligent, responsible, and caring adults do? If his schooling experiences continued to develop his interests, inquiry, knowledge and skills, perhaps Campbell has grown up to study marine engineering and conservation. If so, there would be little doubt Campbell would be the kind of "productive, economic citizen" some societies' curricular documents promote, as well as being a citizen and contributor to concerns about world sustainability issues.

These ideas represent a dynamic and evolving curriculum. Therefore, they also align with Bruner's (1996) later proposal in his book *The culture of education* that curriculum "is like an animated conversation on a topic that can never be fully defined ... animated ... because it is always lively if it is honest, but also because one uses animation ... props, pictures, texts, films, and even "demonstrations" (p. 116). This description of an ongoing conversation between teachers and children that is supported by planned and spontaneous resources, equipment and experiences has a good alignment with interests and play-based ECE provision in the way articulated in this chapter. From this perspective, culture is the context for understanding meanings and interpretations of both

interests and content, and also the means to innovate and go beyond what is known. This view is important to instil/enable in young children as our conceptualization of interests shows that they are inquirers into their worlds, and might be keen to/encouraged/prompted through ongoing interests that involve inquiry and identity development to innovate and problem-solve on a larger scale later in their lives.

The spiral notion refers to curriculum making as beginning with selected principles and information aligned with children's intuitive and other early interests-based understandings that is returned to in a recursive, iterative and increasingly complex manner many times throughout education. The example of Faizah offers a snapshot from this dynamic spiral of curriculum making in which the teacher used the nursery car wash as a meaningful context for building upon children's understanding of scientific and mathematical concepts. Over time, these concepts could be revisited so as to enable Faizah's interests to lead to deeper learning in a widening range of contexts. Bruner was clear that no knowledge is beyond children's understanding and that the teacher's role was to locate the ideas of interest and grow the child's learning through careful and deepening provision of experiences and scaffolding of topics/knowledge/subjects. Understanding, rather than the performance of decontextualized academic achievement, was Bruner's focus.

Clearly this spiral curriculum, learning and education can begin in ECE where interests are valued as a source of curriculum that can build knowledge. This is an idea Bruner championed long ago to redress concerns about the didactic nature of teaching, a concern that has crept into ECE over the years through a decontextualized focus on school readiness as being achieved through teacher-led approaches. As a longstanding scholar of education, Bruner's ideas about "readiness" in 1960 were these of a child-focused approach to curriculum making that kept returning to, and deepening, interests and knowledge. It was not about the imposition of content to reduce so-called academic deficits and socioeconomic disparities, content that would lead to later continued context-free mastery of learning.

The principles of a spiral curriculum in summary form then are content, coherence, extension/expansion, and progression that align with children's ways of knowing and learning. Each principle has implications for the role and responses of a teacher. Selecting *content* involves deep interpretation of interests. *Coherence* involves the revisiting of related ideas and experiences over time and in gradually more *progressive* and *expansive* ways. Notwithstanding this principle, we note that children's learning can take retrogressive steps – the eventual and intended direction of a spiral is upwards, but that may take time and repeated opportunities.

Conclusion

Curriculum decision-making is implicated in political, cultural and economic contexts. In the context of ECE children's interests are commonly included as a source of curriculum in policy documents but have been overridden by concerns about school readiness that lead to decontextualized societal interests as an influence on curriculum. We have offered a conceptualization of curriculum making built on a view of children as competent and capable learners who bring a range of interests to their educational experiences from their participation in families, communities and cultures. We presented three theoretical framings for children's interests, and then argued for sociocultural interpretations as leading to more authentic and dynamic curriculum in ECE. Throughout we offered examples of children's interests and their incorporation into curriculum.

We then offered selected intellectual contributions from Jerome Bruner to show that a more dynamic, relational and responsive approach to curriculum making in ECE can still lead to the kinds of outcomes desired by a society. Consideration of knowledge as "intellectually honest" and curriculum as a "spiral" enables knowledge and curriculum to be led by children and fostered by teachers in ways that meet shared personal, community, political and societal objectives. We suggest that synthesizing funds of knowledge-based interests and Bruner's spiral curriculum can inform new thinking about children's "readiness" in which the focus shifts from current preoccupations with standardized and decontextualized approaches to learning and progress in ECE. Instead, readiness is reframed as a relational process of curriculum making and pedagogical interactions that foster children's motivation to learn in contexts that have meaning and relevance to their everyday experiences and relationships.

Children's participation in curriculum-making as the co-construction of learning content is the focus of this article. As children scarcely (if at all) have a voice in national curriculum development, the examples discussed are about curriculum-making at the local level, that is, with a class or school. Beginning with Indigenous origins of curriculum-making, influential thinking on children's participation in local curriculum-making is described somewhat chronologically, noting key influences such as the conception of mass schooling, UN Convention of the Rights of the Child, Reggio Emilia preschool approach to curriculum, emergent curriculum, mosaic approach, children as citizens, rhizomatic thinking, place-based curricula, and posthumanism.

Origins of curriculum-making

Entangled relations with all entities have informed curricula making for millennia, without demarcating children, curricula and education. By looking to the world's longest living continuous culture, traditional Aboriginal Australian culture (Behrendt, 2016), in which curriculum-making is and has been a shared inclusive relational and organic activity with all entities (plants, skies, waterways, land, climate and animals) they co-exist with (Martin, 2016; Proud et al., 2017) for more than 50,000 years (Devlin, 2016). Children learn with the environment and community, alongside family members sourcing tucker (fish, meat, fruit, vegetables and bush honey) and telling stories (Marika, 2000) to come to know lore and kinship for living peacefully and sustainably with other living beings (Pascoe, 2014). Across in the lands that are now called New Mexico, Tewa science educator Gregory Cajete (1994) describes Pueblo ways-of-knowing-in-being (believed to be more than 1500 years (Duwe, 2020)) as an ecology of relationships porously extending to space and time to holistically be of the world rather than in. And in Aotearoa (now known as New Zealand), Māori, one of the youngest cultures in the world (estimated to be 700–800 years (Anderson, 2016)) enact curriculum-making in which children are accorded mana (respect) and freedom to participate within everyday activities of their whānau (family) and hapū (tribe or clan), accompanied by their Elders imparting myths and legends of the cosmos (Te Rangi Hiroa, 1950). Māori curriculum-making unfolds through responsibly knowing with nature with wise others (Elders).

In western ontologies, the conception of mass schooling from the industrial age led to the regulation of curricula through state authorities. The liveliness of curriculum-making that Bobbitt (1921) described as human activity "in the light of actual human needs" (p. 607) was perhaps more widespread across the globe through master-apprenticeship model prior to the establishment of mass schooling.

Curriculum in contemporary times

In formal schooling, the people involved are mostly students and teachers, with some contribution from families and community members. Across recent decades, curricula has shifted from input regulated to output regulated (Leat et al., 2013), that is, from specification of content to specification of skills, via measurement of performance data (e.g., see Wilkins, 2011). Such cultures of performativity (e.g., Keddie et al., 2011) erode teacher and student autonomy. Curriculum in these neoliberal agendas is firmly under the control of government education policy (Biddulph, 2011). In neoliberal societies, curriculum is nationalized, and standardized to meet global performance targets. The very people school curricula are designed for scarcely have any say or are silenced (Brooker and MacDonald, 1999).

Children's participatory contributions in curriculum-making has been minimally permitted and explored in western education, as it is widely understood and accepted that teachers have the responsibility of curriculum-making (Clandinin and Connelly, 1992) as regulated by state education authorities (Levin, 2007). Formal schooling has in the most been constructed as what Freire (1970) referred to as a banking model in which teachers narrate subject content and students passively listen as containers to be "filled." He proposed instead that such a hierarchy be countered with partnerships between students and teachers and the world through merging of roles (student-teacher and teachers-students) in problem-based curriculum-making. Curriculum studies scholarship further theorizes and advocates for greater agency in curriculum-making, through seeing curriculum as co-created inquiries (Edwards et al., 1998), a lived experience (Dewey, 1938/1998; Aoki, 2005), as an account of teachers and children's lives together in schools and classrooms (Clandinin and Connelly, 1992), as a space of emergence (Biesta, 2004; Jones and Nimmo, 1994), as a rhizomatic practice (Gough, 2007; Olsson, 2009; Chan, 2011), and as a process of living in and through the world with more-than-human entities (Ross and Mannion, 2012). These ideas of curriculum-making, open up voice and agency for children.

Child as social actor

The creation and endorsement of the United Nations Convention of the Rights of the Child (1989) has provided a strong case for children's participation in matters that affect them, in particular Article 12—right to express their views on all matters affecting them and for their views to be taken seriously. Article 13 (the child shall have the right to freedom of expression) furthers a case for children's contributions, and Article 30 (to enjoy his or her own culture, to profess and practice his or her own religion, or to use his or her own language) sanctions each child's diverse participation and contribution. Following the endorsement of the UNCRC in 1989, sociological interest in and attention to children and childhood has grown and formed burgeoning scholarship in sociology of childhood which proposes a view of "children as competent social actors" (James and Prout, 1995, p. 78) "who shape their identities, create and communicate valid views about the social world and have a right to participate in it" (MacNaughton et al., 2007, p. 460). In essence, children are understood as agential, inviting understandings of children as contributors and co-constructors of curriculum-making.

Children as project protagonists and collaborators

The preschools of the Italian province Reggio Emilia have attracted global attention and forged a movement in early childhood education known as the Reggio Emilia approach, for a shift away from a planned curriculum to projects that are co-created between children, teachers and families through a pedagogy of listening and a pedagogy of relationships (Edwards et al., 1998). Malaguzzi (1998) (founder of the philosophy that informs the Reggio Emilia preschools) and Rinaldi (2006) (world leading pedagogist on Reggio Emilia preschools) both explain that the term curriculum (and its associated terms) are not suited for representing the understanding of learning or knowledge in their practice. Instead they propose the word project to describe knowledge and learning creation at Reggio Emilia preschools. Children are understood as protagonists and collaborators in the curation of knowledge-building projects, with teachers as partners, who led curation of children's ideas, interests and activities. Though many romantically idealize the practices of the Reggio Emilia preschools, it is important to realistically recognize the limitations of what children can actually decide on. Preschools are institutions governed by local and national rules and policies, and "even in a democratically functioning preschool, the child structurally has a specifically subordinated position" (Hočevar et al., 2013, p. 485).

Children as curriculum informants

One interpretation of the Reggio Emilia preschool practices was coined emergent curriculum by Betty Jones (Jones and Nimmo, 1994) and employed in early childhood education in other countries (e.g., Australia and the US). In an emergent curriculum, "children's interests, worries, desires, understandings, and activities of learning interest expressed by both children and educators are generated as the beginning points for curriculum" relying on "developmentally appropriate" standards and "well-developed observation skills of early childhood teachers" (Wien and Stacey, 2000, p. 1) to plot in a webbed pattern as documentation of the program/pathways of learning (Nimmo & Jones). Teachers actively look for and follow the interests of the children (Birmer, 2015), documenting a curriculum as it unfolds. The use of the word curriculum is not synonymous with the intentions on the Reggio Emilia approach, as noted earlier. Emergent curriculum is one particular idea of looking to children's interests, ideas and activities as starting points for curriculum-making. Children are positioned as informants but not necessarily active decision-makers of an emergent curriculum.

A suite of research tools known as the mosaic approach developed by Clark and Moss (2001), Clark (2017) in the UK for gathering children's perspectives in the Listening to Young children's study have also been applied as mechanisms for children's input into curriculum-making. The intent of the mosaic approach as a multi-method, polyvocal approach is to "enable young children to create a 'living picture' of their lives" through a range of modes of expression (role play, photos, tours, map making) that are accessible to young children beyond reliance on the written or spoken word (Clark and Moss, 2001, p. 12). Ideas from the Reggio Emilia approach and the New Zealand early childhood curriculum Te Whāriki of listening to children and engaging with them as active

competent participants were influential in the development of the mosaic approach (Clark, 2017). The mosaic approach has come to be known as a framework that enables “teachers to become the researchers of their own class in a flexible, adaptable and fun way that respects and celebrates children’s rights and strengths” (Rouvali and Riga, 2019, p. 999) offering a conduit between adults and children to discuss and negotiate meanings (Clark and Moss, 2005). Children’s perspectives of learning in the world are worked with in curriculum-making on the grounds that this is necessary for children to identify with the educational program, to attend to Brooker’s (2002) provocation that “unless adults are alert to children’s own ways of seeing and understanding and representing the world to themselves, it is unlikely that the child will ever manage to identify with the school’s and teacher’s ways of seeing” (p. 171).

Emergent curriculum and mosaic approach are informed by social-constructivism, which foregrounds collaboration in learning and a strengths-based approach to curriculum-making. Young children are positioned as providers of knowledge and co-constructors of meaning, with teachers as facilitators or opportunity providers rather than definitive managers (Chan, 2011).

Children’s participation in curriculum-making authorized in national curricula

Early childhood curricula in some nations such as New Zealand, Australia and Canada have authorized children’s participation in curriculum-making.

In Aotearoa, New Zealand, the Te Whāriki curriculum was launched in 1996 (updated in 2017) after 5 years of comprehensive community and sector development. A 5-year development duration is a rarity in government-initiated policy, though as one of the curriculum writers, May (2012), explains “it takes time to develop and implement a curriculum that is accepted, inclusive, meaningful and makes a difference for children.” In Māori language, Te Whāriki translates to “a woven mat for all to stand on,” offering a metaphor for teachers, families and children weaving curriculum patterns shaped by different cultural perspectives, ages, philosophies for a child centered curriculum that grows from children’s learning dispositions. Te Whāriki was a landmark curriculum as it was the first bicultural curriculum in Aotearoa, New Zealand. The curriculum foregrounds Maori knowledge and rights and children’s, as Tilly Reedy (Ngati Porou) (1995), a Māori partner on the development of Te Whāriki asserted: “Our rights are recognized and so are the rights of everyone else ... Te Whāriki recognizes my right to choose, and your right to choose too” (p. 13). Children’s rights scholar, Anne Smith (2007), described Te Whāriki, as taonga (treasure) encapsulating aspirations for children based on children’s rights. The curriculum has attracted global attention, with UK esteemed early childhood provision scholar, Moss (2007) observing that through Te Whāriki, New Zealand was “leading a wave of early childhood innovation” (p. 27).

The first national Australian early childhood curricula, the Early Years Learning Framework for Australia (Australian Government Department of Education, Employment and Workplace Relations for the Council of Australian Governments, 2009) drew inspiration from Te Whāriki. The framework explicitly attends to the UNCRC broadly and Article 12 explicitly with recognition of children’s right to be active participants in all matters affecting their lives. When the framework was being developed, the first version welcomed children, educators and families as active, valued contributors to learning, with children’s perspectives and agency in decisions respected and responded to (Millei and Sumson, 2011). In the final version of the framework, children are described as active participants and decision makers, though all mentions of curriculum decision-making are firmly led by educators, such as “all children and families are respected and actively encouraged to collaborate with educators about curriculum decisions in order to ensure that learning experiences are meaningful” (p. 12) aligning more with notions of children as curriculum informants. A survey of Australian early childhood teachers in child care, kindergarten and pre-primary settings implementing the Early Years Learning Framework saw that authentic comprehensive engagement of young children in decision-making was limited, with many seeing making choices, one-off agendas as decision-making and did not mention including children in decisions that relate directly to curriculum structures (Hudson, 2012).

Another example of a national early childhood curriculum which welcomes children’s participation in curriculum-making is the British Columbia Early Learning Framework first released in 2008 and revised in 2019 (Government of British Columbia, 2019). This framework also responded to the UNCRC and sociology of childhood and is framed on a “image of the child as capable and full of potential” (p. 3). Children are also recognized as decision-makers, in fact it is the only mention of decision in the curriculum document. Curriculum is defined as emergent and responsive from the union of children, adults, ideas, and materials, constructing knowledge “in ways that are local, inclusive, ethical, and democratic” (p. 11). The British Columbia Early Learning Framework also implements the United Nations Declaration on the Rights of Indigenous Peoples (UNDRIP) to explicitly decolonize curriculum by honoring First Nation communities and knowledges and contributing to lasting reconciliation and self-determination for Métis children, families and Elders.

These progressive early childhood curriculum documents counter global emphasis on high-stakes assessment dominating schooling practice, policy and decision-making, though the uptake of children’s participation in curriculum-making is in the most found in small pockets, driven by individual teachers who advocate for children’s participation. The lack of resources, knowledge and relevant training on how to listen to children’s voices and how to include them in the decision-making process have been noted as significant hindrances (Rudduck and McIntyre, 2007), along with the continuously increasing curriculum workload, reducing teacher ability to dedicate time to listening to children and children’s participation (Rouvali and Riga, 2019).

Children as citizens in curriculum-making

Democracy as the participatory practice of citizens (Loenen, 1997) in education is not new, it has been discussed and theorized since its inception in the *polis* of Athens. An individualistic conception of democracy in education is based on the thinking of Enlightenment philosophers such as Kant (1784/1992), which translated into curriculum-making emphasizes freedom of expression and choice for individuals. A social conception of democracy in education, based on the influential text *Democracy and education* (Dewey, 1916), emphasizes group cooperation played out through both children and adults considering the direction of actions in reference to others. A political conception of democracy in education, informed by Arendt's (1958/1998) theory of action views the first step as taking initiative (Biesta, 2007). In curriculum-making, it is through actions, that people bring something new into the world that are responded to by others. It is in the interplay of initiated actions and supportive responses to those initiated actions that democracy is practiced.

The positioning of teacher authority reduces student agency and enablement of full democracy in curriculum-making. As mentioned earlier Freire (1970) opposed the banking model of education. Instead he proposed that the relationship between teacher and student be transformed to be equitable, forming a collective in which the democratically minded educator consciously critiques ethics in participation. To Freire (1998), democracy in education is a respectful practice, where teacher and students collaborate and involves teachers respecting the autonomy, identity, and knowledge of students orchestrated through cultivating a balance between freedom and authority.

To authentically embrace children's rights and citizenship in curriculum-making it is not just about making choices, but rather citizenship practices of offering ideas, discussing, deliberating and reaching consensus with groups. To reach a collective decision requires the civic art of deliberation, that is, deliberative in the sense of deliberative democracy, striving for agreement about what to do (collective-will formation) (Samuelsson, 2016). Samuelsson recognizes that attention to deliberative democratic skill building in education has in the most been minimal. Deliberative democracy in curriculum-making involves all members of a learning community having the opportunity to state claims, give reasons, listen to and reflect on others' suggestions and ideas, and work toward locating curriculum un-folding in collaboration with others. Tomas Englund (2006, 2015) offered a roadmap for deliberative democracy in curriculum-making working toward deliberative communication between students without teacher facilitation. Collective will formation processes are at the core of deliberative curriculum-making, that is, reaching joint agreement about what to do. Equitable participation of all parties (students, teachers, community members) in curriculum-making involves decision-making through collective-will formation. Deliberative curriculum-making has been found in empirical studies (e.g., see Andersson, 2012) to increase knowledge, articulation of points of view, civic capacity and participation. Children and young people are more likely to participate in the curriculum if they are active constructors of the curriculum (Enright and O'Sullivan, 2010) and their views have been included (Harris and Manatakis, 2013).

Children in rhizomatic curriculum-making

Application of Deleuze and Guattari's (1987) rhizomatic philosophy as non-hierarchical, heterogeneous, multiplicitous, and acentered to curriculum-making offers a means for organic equitable unfolding curriculum-making. Through such an ontology, preconceptions of children/students and teachers are abandoned with all participants in the learning community engaging in a dynamic ongoing negotiated process of transformational learning (Olsson, 2009). Rhizomatic curriculum-making is a shift away from essentialist curricula based on lack or deficit framing ("you don't know this or can't do this, so I need to teach you"). Curriculum-making approached from a rhizomatic onto-epistemology is multiplicitous, adventitious, nonlinear and nonhierarchical assemblages to other things. Children's desires, ideas, questions are listened to and valued, producing new and multiple thinking, action and creation. Children are not homogenously constructed, rather everyone, regardless of age, is understood and engaged with in a constant state of "becoming." The common becoming of human life is embraced. The British Columbia Early Learning Framework (Government of British Columbia, 2019) recognizes learning as rhizomatic "moving in unexpected and surprising directions as children are in relationships with people, place, ideas, and materials" (p. 25). Rhizomatic curriculum making is therefore "impossible to predict, plan, supervise or evaluate according to predefined standards" (Olsson, 2009, p. 117). Through rhizomatic curriculum-making, all involved form rhizomes with the world.

What spurs rhizomatic curriculum-making is desire, as the state of the unconscious forces and "the principal and primal force in everything, the immanent source of all production" (Chan, 2011, p. 117). Desire fuels curriculum-making produced through rhizomatic mapping. Chan suggests "we must consider the ways in which children's desires can be related to curriculum making. Doing this would require us to think, question, and critically analyze our ways of knowing and to open ourselves to otherness, complexity, and multiplicity" (p. 118). The binary of teacher and student is dissolved, and rather the collective is understood as an education community (children, families, educators, community members) "working together in an ongoing process of constructing and reconstructing the problem" (Chan, 2011, p. 119). Decision-making participation of all parties regardless of age across all domains is welcomed, as opposed to behaviorist model curriculum-making in which teachers emphasize the importance of getting children to make the *right* decisions to follow social and community rules (Hudson, 2012).

Children's curriculum-making with place, home and community

Attention to children and young people's curriculum-making beyond classrooms is growing. Huber et al. (2011) reconceptualize children's curriculum-making as inclusive of family and community members in home and community places, decentering curriculum-making as school-centric. In essence they propose curriculum of lives featuring children, teacher, family and community member identities. Ross and Mannion (2012) applying Tim Ingold's (2000) notion of dwelling and see curriculum-making as a process of living in and through the world with more-than-human entities, beginning "with a concern with the material context of learning and/or the lived experience of participants" (p. 304), so that curriculum is a lived story.

Many across the globe identify with home and community-based curriculum-making and place-based curriculum-making. Through growing movements of un-schooling (learning through life at home and in the community) and place-based education, that may be enacted through forest schools, place-responsive pedagogies, place-conscious pedagogies and environmental education centers. Forest schools see curriculum-making unfolding between child and nature explorations. Place responsive pedagogies create curricula through teachers collaborating with students and others, as historically embodied subjects, who explicitly seek to create new place-based practices and place-based relations (Ross and Mannion, 2012). Place-conscious pedagogies produce curricula through educators with an intimate knowledge of the ecology, history and pedagogical possibilities of the place, engaging students in sharing, questioning, and inquiring (Renshaw and Tooth, 2018). In essence these approaches see curriculum-making unfolding through children's interactions with places, home and community. Children's agency is foregrounded, though not necessarily through explicit collective decision-making.

Decentering the child in posthuman curriculum-making

A posthuman approach to curriculum-making seeks to decenter the child, and more broadly the human centric focus. Fikile Nxumalo proposes an uptake of "both critical posthumanisms and Indigenous relational ontologies that suggest we cannot continue with the universalized, individual human developing child as the center of what we do" (in Nxumalo et al., 2020, p. 199). Rather posthuman curriculum-making invites embracing learning with and from other entities, be they living or inanimate, following their rhythms, instead of all non-human matter being there to serve humans in the education project. Quantum physicist and feminist philosopher Karen Barad (2000) prompts ethical considerations in the decentering of the human in curriculum-making by asking: "what kind of (curriculum and) pedagogy help students (and teachers) to learn about practicing responsible science?" (p. 239) that does not continue colonizing, dispossessing and manifesting ecocide. Barad (2007) offers a theory of agential realism, which applied to curriculum-making, would see curriculum and all other participants emerge in intra-actions. Curriculum and participants are not predefined, but rather they become defined in actions of "learning how to intra-act responsibly within the world" (Barad, 2000, p. 237).

In precarious times of climate crises and global pandemics, sustenance for planet Earth is prime. Kroeger and Myers (2019) propose that curriculum enhances children's understanding and centrality with Earth, so rather than placing the child at the center of the curriculum (such as developmentally appropriate curriculum, Reggio Emilia approach, emergent curriculum, mosaic approach), it is the Earth that is at the center. Drawing from critical, feminist, Indigenous, post-colonial, post-foundational and post-human ideas, they propose that curriculum-making is a more-than-human activity of reciprocal relations between Earth, Elders and children. And to attend to the global crises, the United Nations asserts that it is necessary that children and youth are actively included in international communities "to achieve peace, security, justice, climate resilience, and sustainable development for all" (Clark et al., 2020, pp. 616–617).

Conclusion

Batched approaches to teacher-led curriculum are not working as demonstrated through the most frequent unproductive behavior evidenced by teachers being disengaged behavior (Sullivan et al., 2014). Children need to feel connected to the curriculum to be motivated to learn, otherwise they switch off from teacher directed learning and partake in disruptive practice (Rudduck and Flutter, 2000). Children feel connected to the curriculum if they contribute to curriculum-making so that the curriculum aligns with their interests, needs, strengths, capabilities and pace (Subban, 2016). They then are more likely to experience school education as relevant, valuable preparation for life. Education prior to formal schooling often has greater freedoms to collaborate with children and families to collectively make curricula, as in the examples provided by Quintero's (2015) book on child-led participatory curriculum. Compulsory schooling years are regulated by state written standardized curricula, restricting school freedoms to hear from the very people education is designed for through children's participation in curriculum-making. Independent and community governed schools are more likely to welcome children's participation in curriculum-making. The COVID-19 global pandemic has interrupted and shaken education in monumental ways that require reconceptualizing education and curriculum-making so that the voice of children is heard to ensure curricula is relevant and customized to their precarious and precious lives.

Introduction

While education has traditionally been utilized for instrumental social and political reasons by governments worldwide, the 21st century has heralded an intensification of such tendencies, especially visible in profound changes to the framings of school curriculum policy. These changes, characterized as the “new curriculum” (Priestley and Biesta, 2013), have been transnational in scope, driven by significant discourses produced and disseminated via major institutional actors on the world stage, such as the OECD, the European Union and UNESCO (e.g., Zapp, 2019; Lingard, 2021). For example, the OECD’s *Education 2030* initiative has a strong focus on curricular purposes, relevance and currency in a fast-changing world, and the forms of knowledge and competence required in that world (OECD, 2018). The discourses at the heart of *Education 2030* both drive and reflect emerging policy trajectories worldwide, as its publications have emerged from discussions involving key education stakeholders from many countries, including policymakers. Key policy themes associated with new curricula include common approaches to curricular regulation, focus, and school autonomy.

In relation to curricular regulation, there have emerged changed methodologies for the mobilization of policy to frame practice in schools. This is most evident in the shift from input regulation to output regulation (Nieveen and Kuiper, 2012; Leat et al., 2013). The former relates to specification of content to be taught; the latter concerns the measurement of outputs, for example using attainment data and performance indicators to evaluate the effectiveness of schools and teachers. This changed emphasis is strongly associated with changes to the technical form of the curriculum (Luke et al., 2012). National curricula now tend to be presented as highly technical curriculum frameworks, articulated through learning outcomes structured into linear and hierarchical levels, which can be utilized to evaluate the performance of individual students, as well as schools and teachers. These policy approaches have been heavily critiqued for contributing to a performative culture in schools and eroding teacher autonomy (e.g., Kelly, 2008; Luke et al., 2012; Priestley et al., 2015). Changes in the form of curricular regulation are linked to changes to the focus of the new curricula. A shift from the specification of substantive knowledge/content to genericism has been well-documented and subject to criticism by many writers (e.g., Young, 2007; Yates and Collins, 2010; Young and Muller, 2010). This trend has been accompanied by a strong emphasis on skills/competencies. Sinnema and Aitken (2013) point to transnational commonalities in curricula. They highlight common goals for curriculum policy, including the use of curriculum as a lever for improvement and to promote equity. They identify common new emphases in policy: competencies, values, pedagogy, student agency, partnerships and reduced prescription. This final emphasis is an important – and contradictory – aspect of new curricula. On the one hand, there has been strong rhetoric about reducing prescription, enhancing school autonomy, empowering schools and teachers, and promoting local choice in building curricula in schools (e.g., OECD, 2018; ICEA, 2018); on the other hand, and as noted above, the recourse to output regulation – including the use of curricular frameworks to monitor performance – has the potential to diminish teachers’ professional agency, and to narrow the scope for local curriculum making as a creative and innovative pedagogical process.

In the above-described context, two concepts assume great importance. These are curriculum making and teacher agency. Curriculum making – the idea that the curriculum is constructed in different educational contexts such as policymaking arenas, national and local agencies, schools and classrooms – has a long history, for instance being coined by Bobbitt (1921) over a hundred years ago, albeit with a very different meaning to its later theorization, which is also the focus of this chapter. Bobbitt used the term in a way closer to the technical manner described above and which prevails in curriculum policy today, with a strong focus on a “scientific method” in education. Teacher agency is a relatively new concept, which has become prominent in the past decade in different forms (e.g., Pyhältö et al., 2014; Priestley et al., 2015). The first concept is important insofar as the changing discursive and policy landscape is opening up new possibilities for curriculum practice; this requires new understandings of how curriculum, as a set of social practices, is made in different settings. The latter idea is a vital accompaniment to the first, as strongly developed professional

agency is required to maximize possibilities for constructive curriculum making in those different settings. In this chapter, we will first provide an overview of the concept of curriculum making, including some recent conceptual developments that have some resonance for the changing curricular landscape described above. We then explore the concept of teacher agency, offering an ecological understanding of agency as something that is achieved in specific situations. This is a temporal/relational view of agency, which is highly relevant to the creation of propitious conditions for curriculum making. Finally, we conclude the chapter by examining the complex interplay of the two concepts; both the implications of teacher agency for curriculum making, and vice versa (as constructive engagement by teachers in curriculum making across different sites is a means for the development of teacher agency).

Curriculum making

We first explore the concept of curriculum making. The discussion that follows relates to different types of curriculum making across different settings within education systems; while the primary focus of the chapter is on curriculum making by teachers, and their professional agency, it is important to locate these issues within a wider systemic understanding of curriculum making. We preface this section with three key ideas, before exploring the concept of curriculum making. The first is that the school curriculum can be defined as “the multi-layered social practices, including infrastructure, pedagogy and assessment, through which education is structured, enacted and evaluated” (Priestley, 2019, p. 8). We wish to draw attention to three linked dimensions of this definition. The first is the idea of curriculum as social practice; in other words, curriculum is something that is done, or made, by people working with one another in particular social settings of schooling. The second dimension is that the curriculum is made in different ways within and across various layers or sites of education systems, for example schools and national agencies, and is not confined to classrooms. The third dimension concerns the different practices which comprise curriculum, such as selection of knowledge/content, pedagogical approaches and the organization of teaching.

The second idea is that curriculum making is systemic. According to Connolly, curriculum:

... is a complex system involving teachers, students, curricular content, social settings, and all manner of impinging matters ranging from the local to the international. It is a system that needs to be understood systemically. The question is not which of the various factors explain high achievement, the current crime-solving model at work in the literature, but, rather, how it all works together.

Connolly (2013, p. ix).

This implies that changes to one part of the system will inevitably exert effects (often unintended) on other parts of the system.

The third idea is that practitioners mediate curriculum policy, even within the most prescriptive and “teacher-proof” policy framings. This process is subject to many variables, for example beliefs (Priestley et al., 2015), school culture (Cuban, 1998), the nature of their networks (Hizli Alkan and Priestley, 2019), external demands such as accountability, the resources available to teachers (Luke et al., 2012), and notions of teacher professionalism (Kontovourki et al., 2018). Mediation can be constructive, focused on educational purposes, local conditions and the needs of students; or it can be more subversive and instrumental (e.g., Bowe et al., 1992; Osborn et al., 1997; Supovitz, 2008; Braun et al., 2011). This sort of active curriculum making is both inevitable and a desirable activity for professionals. As Doyle (1992, p. 69) suggested, it is important that curriculum making is “a deliberative process of interpretation, judgment and responsibility”.

The above ideas – curriculum as social practice, curriculum as a system, and the ongoing mediation of curriculum by practitioners – pose a serious challenge to prevailing linear product/implementation/delivery conceptions of curriculum that hold sway in many education systems. In particular, they point to the importance of thinking holistically about how policy is framed, and enactment supported. We will come back to this issue in the later sections of the chapter, but first we will explore some ideas about how curriculum operates as a system.

There is a rich vein of literature which has sought to theorize the ways in which curriculum is made systemically. Goodlad’s (1979) seminal work suggests three “levels” of curriculum – the societal, institutional, instructional (he later added a fourth level: the personal). Goodlad’s model was criticized as linear and as hierarchical, partly due to the term “levels”, and despite his emphasis on the transactional (negotiation) and two-way flows of communication, and the positioning of the levels as institutional sites, rather than as forms of activity. Later writers have sought to rework this thinking to address these critiques, but essentially keeping the conceptual framing of levels. Doyle (1992) posited two levels: institutional and classroom levels that represent “distinct but interrelated domains of curriculum discourse, and thus, different types of curriculum processes” (p. 69). Doyle’s institutional level comprises two aspects: 1] the abstract or ideal, a conversation connecting schooling and society; and 2] the analytical or formal, which produces practical curriculum programmes. In his view, however, this is not a linear or hierarchical process; Doyle saw teachers as active “curriculum makers who guide students through the texts, shape the interpretations that are allowed on the floor, and, importantly, define the tasks that students are to accomplish with respect to these texts” (p. 76). More recent writing by Deng (2012) posits three levels: [1] societal (ideal or abstract); [2] programmatic (technical or official); [3] classroom (enacted). Deng similarly does not see this as a linear process; in his view, translation across levels means that a school subject, for example, is not the same as the discipline[s] it derives from, and “classroom curriculum making entails transforming the programmatic curriculum (embodied in curriculum materials) into ‘educative’ experiences for students” (Deng et al., 2013, p. 7).

An alternative approach to defining curriculum making levels has been developed by [Thijs and van den Akker \(2009\)](#). This is a more fine-grained typology, which in a sense challenges curriculum-as-intended/prescribed versus curriculum-as-enacted/experienced binaries, utilizing the following terminology: supra (international); macro (national/system); meso (school/institute); micro (classroom/teacher); and nano (pupil/individual). However, the primary focus of this approach is on curriculum products (e.g., frameworks, programmes of work, etc.) rather than on processes. It can be critiqued on the grounds that it reifies the institutional settings; it does not allow, for example, easy theorization of how actors situated within a particular level (e.g., school) might contribute to curriculum making in other levels (e.g., teachers as curriculum policymakers). Nor, in common with earlier and less fine-grained theorizations explored above, does it easily take account of curricular components such as professional support infrastructure, which sit between schools and policy making, and which are key components in supporting effective curriculum making in schools.

In our recent work on curriculum making ([Priestley et al., 2021b](#)), we have sought to elaborate these approaches, utilizing the Thijs and van den Akker typology (supra, macro, etc.), while adapting it to reflect the insight that curriculum making, as social practice, occurs within different sites of activity across the system. We offer the following caveats. First, the typology should not be read as a hierarchy of levels or layers. Instead, it is a heuristic to analyze curriculum making from the inside out or bottom up, as well as top down, illustrating two way flows of influence, information and activity between the various layers. Second, we do not position sites as institutional levels or even institutional sites of formal or prescribed activity. Instead, these are types of curriculum practice that occur across education systems, as curriculum is made and remade in different contexts. These sites engage various social actors, often moving between sites, and/or present in more than one site, or actors adopting multiple identities, for example teachers as teacher educators (e.g., subject-area counsellors in Cyprus; see [Kontovourki et al., 2021](#)), or teachers as members of curriculum policy committees (e.g., [Theodorou et al., 2017](#)). This heuristic is illustrated in the diagram in [Fig. 1](#), below, showing the sites of activity (e.g., meso), examples of actors (e.g., teachers), and types of activity (e.g., lesson planning).

Curriculum making comprises many types of social practice in distinct contexts within an education system; in Westbury's (2008, p. 49) words, "loosely coupled settings for curriculum decision making are in fact contexts associated with very different activities". These practices produce various forms of curriculum in diverse settings, for example prescribed, described, enacted, and received, and occur for multifarious purposes, for example discourse generation, policy production, program design, pedagogy.

Fig. 1 Sites, actors and activities. Source: [Alvunger et al. \(2021\)](#).

There might be two-way or even multiple-way relationships between or cutting across different sites of activity. For example, policy making may be shaped by both supra discourses and by diverse local imperatives; curriculum making in schools is likely to be shaped by a variety of mediating conditions, only one of which may be a top-down policy prescription.

The focus on sites of activity rather than institutional settings, means that the heuristic is not a normative framework stating how curriculum making should occur; instead, it is an analytical tool for understanding how curriculum making occurs and emerges in different contexts – and for understanding both the considerable variation from country to country and the historicized complexity from context to context within countries. This is, as we shall demonstrate in later sections of the chapter, important and perhaps necessary when we theorize teachers as social actors and consider how teacher agency might be enhanced.

Teacher agency

We next examine the concept of teacher agency. This is an important concept in relation to curriculum making, for the reasons already outlined: the inevitability (and indeed desirability) of teachers mediating curriculum policy; the need for teachers, in the words of Doyle (1992, p. 77), to be “responsible curriculum theorists”; and recent contradictory trends in curriculum policy to position teachers as agents of change and active curriculum makers, while simultaneously undermining the conditions within/through which they can achieve agency. The latter point thus needs to be understood against a backdrop of complexity in teachers’ professional lives, particularly tensions within and between policies, which create dilemmas, encourage teachers to play safe (e.g., instrumental selection of content, teaching to the test, etc.) and effectively reduce teacher agency (e.g., see Priestley et al., 2015; Smith, 2019). The ecological understanding of agency (Priestley et al., 2015), which we expound in the following paragraphs, offers a practical approach to understanding this problem.

This approach to understanding agency approach differs from traditional sociological accounts of agency in significant ways. First, the ecological understanding posits agency as an emergent phenomenon, rather than as a variable in social action, as it is often characterized in the longstanding structure/agency debate.

[T]his concept of agency highlights that actors always act *by means of* their environment rather than simply in their environment [so that] the achievement of agency will always result from the *interplay of individual efforts, available resources and contextual and structural factors as they come together in particular and, in a sense, always unique situations.*

Biesta and Tedder (2007, p. 137); emph. added.

Agency is, therefore, not something that a person possesses; it is something that people do or, more precisely, something they achieve (Biesta and Tedder, 2007). In this understanding, agency is thus a “quality” of the engagement of actors with temporal-relational contexts-for-action, rather than an innate quality of the actors themselves.

This ecological understanding of agency draws heavily on the social theory of Emirbayer and Mische (1998), which suggests that agency is always shaped by the dynamic interplay of three temporal dimensions – influences from the past, orientations toward the future and engagement with the present – and which takes into consideration “how this interplay varies within different structural contexts of action” (Emirbayer and Mische, 1998, p. 963). Emirbayer and Mische refer to these three dimensions as the iterative, the projective and the practical-evaluative. All three dimensions play a role in social action, but the degree to which they contribute varies, thus agency may be oriented more or less, and variably over time and across different contexts, toward past, present or future influences. Emirbayer and Mische refer to these variable influences as a “chordal triad of agency within which all three dimensions resonate as separate but not always harmonious tones” (Emirbayer and Mische, 1998, p. 972; emphasis in original). Thus, they define agency as “the temporally constructed engagement by actors of different structural environments – the temporal-relational contexts of action – which, through the interplay of habit, imagination, and judgement, both reproduces and transforms those structures in interactive response to the problems posed by changing historical situations” (Emirbayer and Mische, 1998, p. 970; emph. in original). Agency therefore manifests as a “temporally embedded process of social engagement, informed by the past (in its habitual aspect), oriented toward the future (as a capacity to imagine alternative possibilities) and ‘acted out’ in the present (as a capacity to contextualize past habits and future projects with the contingencies of the moment)” (Emirbayer and Mische, 1998, p. 963).

Priestley et al. (2015) have applied this ecological understanding of agency to the professional work of teachers (see Fig. 2 below).

This diagram illustrates the key dimensions of teacher agency, enabling an analytical separation of the key elements of each dimension in the chordal triad. In respect of the iterative dimension, the model draws attention to the influence of the more general life histories of teachers and their more specific professional histories (which include both their own education as a teacher and the accumulated experience of being a teacher). This draws attention to the fact, as we earlier stated, that while agency is not merely personal capacity, such capacity – for instance beliefs and values, professional knowledge and confidence – is an important component of teacher agency. This in turn draws attention to the importance of good teacher education and rich professional experience to foster future agency.

The projective dimension of teacher agency relates to teachers’ abilities to form professional aspirations – both long term and short term. Such aspirations may be positive in nature, relating to the development and welfare of students (Lasky, 2005), and lead to agency that is protective of students’ interests. Future oriented agency may support policy intentions, or it may act in resistance to

Fig. 2 An ecological understanding of teacher agency. Source: [Priestley et al. \(2015\)](#).

them ([Osborn et al., 1997](#)). Conversely, aspirations may be more narrowly instrumental, for example underpinning selection of content to support teaching to the test ([Smith, 2019](#)), or geared to maintaining a “normal desirable state” in the classroom ([Brown and McIntyre, 1992](#)).

The iterational and projective dimensions of agency are anchored in past experience, and to a large extent involve personal capacity. The practical-evaluative dimension, conversely, is more directly related to the present context – that is, the day-to-day working environment within which teachers work – by means of which agency is achieved. Teaching is a profession rife with ambiguity and professional dilemmas (e.g., [Helsby, 1999](#)), context dependent and contestable in terms of its aims (e.g., [Kontovourki et al., 2018](#)). Teachers make daily decisions that are difficult, often conflicting with their aspirations, and often with insufficient time to reflect and to engage in professional dialogue with colleagues. The practical-evaluative dimension powerfully shapes agency. This is practical, both offering affordances for agency (for example, making available resources) and inhibiting it (for example, imposing barriers to action through the exercise of coercive power). It is also evaluative, for instance being shaped by judgments relating to risk and cost/benefit. The practical-evaluative dimension of agency involves various types of affordances and constraints: cultural (e.g., access to cognitive resources, ideas); structural (e.g., relational resources available via teacher networks); and material (e.g., the physical layout of schools and classrooms).

Here, we have set out a brief summary of some key aspects of an ecological understanding of teacher agency. For a more detailed account of this conceptualization of teacher agency, readers should refer to [Priestley et al. \(2015\)](#). We now proceed to the concluding section of this chapter, where we further explore the dynamic relationship between the twin concepts of teacher agency and curriculum making.

Teacher agency and curriculum making

Teacher agency and curriculum making are mutually constitutive concepts – a chicken and egg situation, to draw upon a well-used metaphor. This echoes to some extent [Stenhouse's \(1975\)](#) observation that there can be no curriculum development without teacher development. Two facets are of crucial importance in understanding how teacher agency is essential for constructive curriculum making by teachers: personal capacity, in terms of professional knowledge, beliefs, dispositions and confidence, as well as the ability to form expansive aspirations for practice; and the affordances for agency that are available in the professional contexts within which, and by means of which, teachers work. Conversely, curriculum making as social practice – especially where actors move across sites – affords important experiences and resources, originating from different settings/environments in an interplay between actors and different agendas, for fostering and enhancing teacher agency. A key question is, thus, “how can systemic thinking and deliberate action across multiple sites of activity enhance teacher agency?”. We contend that “a better understanding of the processes of curriculum making, which reveals such complex underlying and regulating dynamics, would facilitate and enable social actors’ agency toward curriculum change” ([Alvunger et al., 2021](#), pp. 273–4). In this section of the chapter, we first illustrate how teacher agency can enhance curriculum making. We then examine how nuanced understandings of curriculum making might provide the insights for further enabling teacher agency. We conclude with some reflections about how policymakers, teacher educators and school leaders might act differently to develop the professional agency of teachers and facilitate more constructive and meaningful curriculum making in schools.

An important question relates to why teacher agency is important for curriculum making? We do not have the space to examine this question in depth, however, a wealth of research literature over the past 30 years has explored the consequences of teacher-proof policy that seeks to reduce the teacher's role to that of a technician, simply delivering prescribed policy. These include "playing the game" (Gleeson and Gunter, 2001); a game that can take the form of fabrication of the school's image through careful impression management and discourses of excellence (Keddie et al., 2011), the concealing of "dirty laundry" (Cowie et al., 2007), and more serious corruption and cheating (Ball, 2003; Sahlberg, 2010). Recent literature has highlighted the dangers associated with curriculum making that is too tightly focused on meeting external demands, for example instrumental selection of knowledge/content (Smith, 2019) and curriculum narrowing (Shapira and Priestley, 2020). Moreover, as we illustrated previously, teacher mediation of policy is an inevitability, and needs to be enabled constructively; hence there is also need to foster teacher agency.

Teacher agency for curriculum making

Curriculum making is inherently a social practice. It "involves an interplay between different actors, contested spaces and power relations, framed by particularities and contextual factors of social practices, shaping unique settings, and producing multifarious meanings of what curriculum is and for whom it is made" (Alvunger et al., 2021, p. 274). There is considerable resonance here with the ecological understanding of agency, which is also contingent on conditions, "such as the room for maneuver and conceptual resources of policy, as well as the beliefs, values and professional knowledge of the participating stakeholders" (Alvunger et al., 2021). But what does this mean in practical terms? We offer here some examples, structured around the three temporal dimensions of the chordal triad.

The iterational dimension of agency concerns "*the selective reactivation by actors of past patterns of thought and action, routinely incorporated in practical activity, thereby giving stability and order to social universes and helping to sustain identities, interactions, and institutions over time*" (Emirbayer and Mische, 1998, p. 971; *emph. in original*). A key word here is "selective". Agency is not about following habit – going with the flow – but is, for example, about recognizing, appropriating and refashioning past patterns of behaviors and experience in order to maneuver among repertoires in dealing with present dilemmas. The richness of prior experiences (both professional and personal) appears to be a key factor here. Iterational aspects that contribute to teacher agency include personal capacity (skills and knowledge), beliefs (professional and personal) and values. An important consideration is how teachers might become more agentic in the future. This points to the value of good professional education, for instance approaches based around collaborative professional enquiry, which aim to stimulate deep reflection on practice in relation to educational purposes, and which offer interruption to existing ways of thinking enquiry through, for example, engagement with academic reading (e.g., Priestley and Drew, 2019). Furthermore, professional education constitutes only a small part of the formation of teachers' professional experience. Day to day experience in schools – dialogue with colleagues, exposure to school culture, and other professional engagement is also significant, and it is likely that some contexts, such as highly performative cultures that serve to deprofessionalize teachers, will have long term consequences on future teacher development and professional agency (Priestley et al., 2015). Curriculum making requires rich experience; teachers are only able to maneuver between repertoires if they possess knowledge and reflexive understanding of the different possibilities, and research (e.g., Swann and Brown, 1997; Priestley and Minty, 2013) suggests that a more usual scenario in the face of mandated curriculum reform is to fit existing practice to the requirements of new policy, tweaking where necessary and engaging in strategic compliance in relation to terminology and paperwork. Capacity building, including via formal teacher education, would thus seem to be an essential prerequisite to successful curriculum making, as illustrated, for example in Finland's approach to collective sense-making (Soini et al., 2021).

A key implication here, is that teachers able to draw upon a rich reservoir of experience might develop the capacity to envisage more expansive alternative visions about their future practice, than might be the case with less experienced colleagues. Emirbayer and Mische recognize, that agency is "motivated," including possible intentions to bring about a future that is different from the present and the past. This is encapsulated in the projective element of agency, which encompasses "*the imaginative generation by actors of possible future trajectories of action, in which received structures of thought and action may be creatively reconfigured in relation to actors' hopes, fears, and desires for the future*" (Emirbayer and Mische, 1998, p. 971., *emph. in original*). Research in Scotland (Priestley et al., 2015) suggests that many teachers are effective in achieving short- and medium-term goals, for example getting through the lesson smoothly, or focusing on the attainment levels of their students. However, this research suggests a fairly narrow engagement with consideration of the longer term "effects" of education, and moreover a limited imaginary about what constitutes educational practice. Again, capacity-building through teacher education, particularly with a focus on purposes of education and linked to alternative practices, would seem to be an important prerequisite for curriculum making. Our key argument here is that, in contrast to common-place discourses about teacher-proof curricula, "to ensure a high-quality curriculum, we should educate curriculum-proof teachers, who are skilled and knowledgeable, and able to consider and reflect, and to modify the curriculum to meet their own ends and the ends of their students, regardless of the quality of the curriculum-as-product per se" (Alvunger et al., 2021, p. 285).

Although agency is influenced by orientations to the past and the future, it is exercised in the present. This relates to the practical-evaluative dimension, which entails "*the capacity of actors to make practical and normative judgements among alternative possible trajectories of action, in response to the emerging demands, dilemmas, and ambiguities of presently evolving situations*" (Emirbayer and Mische, 1998, p. 971, *emph. in original*). As we indicated previously, judgements are both practical, shaped by the affordances and constraints of particular contexts for action, and evaluative, for example influenced by perceptions of risk. Contexts for action

comprise cultural, structural and material elements. This insight has significant implications for curriculum making. Highly performative cultures, and/or hierarchically structured education systems can impede or restrict the scope of curriculum making; through constraining possibilities for action and rendering certain courses of action risky in terms of, for example, a school's reputation and/or the career/material interests of the teachers; and by rewarding certain instrumental behaviors such as teaching to the test or curriculum narrowing (Priestley et al., 2015). Conversely, contexts may provide the necessary resources for curriculum making, for example material resources (e.g., textbooks, computers), cultural resources (e.g., access to new ideas) and structural/relational resources (e.g., teacher support networks).

Curriculum making for teacher agency

As we have emphasized, agency is not a quality of the individual, but a property that is achieved through the interplay of individual capacity and contextual conditions. In the case of teacher professional agency in respect of curriculum making, we argue that it is constructed, developed and achieved through engagement in professional activities associated with the processes of curriculum making. We contend that participative and collaborative processes, leading to collective knowledge creation, are especially powerful in fostering teacher agency. This requires holistic system thinking, so that curriculum making across educational systems is joined-up, so to speak, and actively enhances teacher agency across different sites of activity.

Macro policy formation should thus be undertaken with teacher agency in mind. We offer several observations in relation to how this might be addressed. First, there is the issue of regulation. This raises questions about the extent to which governments and national agencies should specify content and pedagogy, and the degree to which local actors such as teachers should have autonomy in these matters. As we have illustrated in this chapter, too much regulation can stifle innovation and lead to instrumental curriculum making in schools. Conversely, too little regulation can deprive practitioners of the resources needed to be effective curriculum makers. Both approaches diminish teachers' professional agency. Furthermore, the wrong type of regulation – the technical form of the curriculum (Luke et al., 2012) – can impact negatively upon teacher agency, with the potential, if linked to accountability systems and performance indicators, to drive performative cultures in schools. Second, there is the question of who is involved in macro curriculum making. There is emerging evidence in the current Welsh curricular reforms (e.g., Priestley et al., 2019) that involvement by teachers in the formation of national policy has had a significant impact upon their curriculum making capacity, and their subsequent agency in leading curriculum reform in their own schools and districts. Third, there is the significant role that national policy makers can play in the development of meso infrastructure to support curriculum making.

Evidence from the European cases featuring in our edited collection *Curriculum Making in Europe* (Priestley et al., 2021a) suggests that meso curriculum making is highly significant for both supporting curriculum making in schools and fostering teacher agency.

[T]he meso site of activity emerges as a space “in between”, where ideas and experiences of nano and micro curriculum making meet supra and macro curriculum making. The meso site of activity is, in a way, comparable with a “melting-pot”, where policy, support and guidance on curriculum making are (although with varying success) provided, coordinated and communicated.

Alvunger et al. (2021, p. 282)

Meso curriculum making is a highly complex and multi-dimensional process, which needs to account for the porous and fluid borders between sites of activity. From our European cases, it is clear that it can take many forms, and is undertaken by many different actors, organizations and individuals, including government agencies, private brokers and companies, and bottom-up practitioner initiatives. It is clear that there is increasing interest, in many European systems at least, in developing meso curriculum support, although we also note the risks involved when a putative devolution of state control, accompanied by rhetorics of school autonomy and empowerment, continues to heavily focus heavily on systems for evaluation and audit, along with an emphasis on professional development for teachers stressing instrumentality and performance, rather than engagement with curricular questions. Well-established meso structures provide teachers with the opportunities to work beyond their immediate professional settings, to work collaboratively and develop networks with colleagues from other settings, and to enhance their relational resources (Priestley et al., 2015). This moving of teachers across sites can, in turn, enhance teacher agency, improving confidence, broadening aspirations, changing professional dispositions, and providing the tools – curricular literacy – to enable teachers to act in and respond to environments restrained by accountability and performativity culture (e.g., Priestley and Drew, 2019).

Finally, we briefly reflect on how curriculum making in schools (micro and nano sites) might be utilized to enhance teacher agency. Issues are cultural and structural. Systematic approaches to develop sense-making are important, to provide a vision, to facilitate engagement with new ideas, and especially to develop relational working. In this latter respect, Priestley et al. (2015) documented two high schools with differing approaches to relational working – one predominantly hierarchical, and the other with well-developed horizontal relational structures. In the former case, the authors reported a lack of teacher agency, characterized by low confidence and general confusion about curricular aims and practices; in the latter case, they witnessed more developed teacher agency in respect of the curriculum reforms being undertaken. These effects were evident in both micro and nano curriculum making in the schools. Teacher agency is especially important for the nano curriculum making site, where teachers and students negotiate the often conflicting demands created by the intersection of official goals, teacher lesson plans, student biographies and the contingencies of daily classroom life. Such transactions are invariably uncertain and

messy, emergent and will often diverge considerably from the intentions set out in national policy. We suggest that school leadership plays a significant role here, in creating the curriculum making spaces and practices that foster teacher agency, including establishing relational structures and the time to utilize them, providing resources (e.g., computers, textbooks), instigating the development of a vision for curriculum making, and affording permission and protection for innovation (both necessary to mitigate risk). Conversely, bottom-up influences can significantly enhance teacher agency through the provision of a rich vein of resources for micro and nano curriculum making, for example as captured by [Leat and Thomas \(2019\)](#) in their studies of community curriculum making.

Concluding thoughts

We conclude by reiterating our argument that teacher agency and curriculum making are mutually constitutive concepts. Teacher agency is necessary for the practices that comprise meaningful curriculum making in schools; if we are to see curriculum making as enactment across multiple sites, this requires pre-existing teacher agency, viz. teachers who are able to maximize the resources afforded by those contexts. Conversely, curriculum making across multiple sites has the potential to develop teacher agency, through the very act of curriculum making in different contexts, particularly in respect of the new experiences gained and the cross-fertilization of ideas that occurs when teachers interact in this way. We suggest the following implications of viewing the concepts in this way.

The first concerns participatory curriculum making. As we point out in our book, *Curriculum Making in Europe*, drawing upon insights gleaned from nine countries cases, “curriculum making strategies that allow actors to experience themselves as trusted and capable participants in curriculum making and make sense of it together with others are the most effective ones – ‘effective’ meaning here that people relate to the aims of the curriculum they co-construct and feel ownership, and through that are willing to adapt and develop not only curriculum, but also the educational system and settings within which they work” ([Alvunger et al., 2021](#), pp. 288–9). The second implication relates to accountability based on trust. We have illustrated how high-levels of top-down accountability and mistrust in practitioners have the potential to drive performativity, narrow curriculum making, lead to system-gaming and undermine professional responsibility. We would argue that there needs to be more trust in teachers, as highly qualified graduate-level professionals, accompanied by the resources for those professionals to work with that trust. Conversely, trust requires capacity-building, and we would argue that curriculum making needs to be supported by quality inputs (resources, support and professional education), rather than being dominated by a focus of measurement of outputs. Third, we point to the importance of middle ground and mobility. Meso activity is clearly indicated in all of the European case studies as being a significant and essential component of curriculum making in schools, even when conspicuous by its absence, particularly as a conduit to enable engagement with policy ([Priestley et al., 2021a](#)). We argue that a systemic and holistic approach to curriculum making should include strategies to enable actors to move between sites (which promotes learning and sense-making), and that these sites should include the in-between space provided by meso sites of activity. Finally, we make the case for a more balanced approach to curriculum regulation. This involves ensuring that regulation is neither too directive nor too unspecific. The former restricts through a spiral of specification ([Wolf, 1995](#)); the latter denies practitioners the cultural resources required for teacher agency. Moreover, there needs to be care, to ensure that policy frameworks do not set up impossible dilemmas for teachers, for example a tension between curricular aims and accountability practices. All of the above require systemic thinking by the architects of curriculum policy, and we would argue that this means appropriately involving the local experts (e.g., teachers) in macro curriculum making, both to design policy frameworks, but also to establish the meso infrastructure needed for effective enactment. We are not advocating here a bottom-up approach where responsibility is handed over mainly to teachers; as [Nieveen and Kuiper \(2021\)](#) have illustrated in respect of the Netherlands, this can lead to a narrowing of expertise. Instead, we advocate a whole system approach, which involves different types of expertise in symbiosis, and which serves in turn to enhance the agency of participants and the collective capacity of the system to engage in curriculum making. We acknowledge here that simply adding teachers to curriculum working groups does not guarantee that their voices will be articulated or even heard; research has demonstrated that issues relating to pre-existing hierarchies, expectations about roles, [lack of] trust and teacher confidence and capacity can limit their involvement in such groups (e.g., [Kirk and MacDonald, 2001](#); [Priestley et al., 2019](#); [Bradfield and Exley, 2020](#); [Theodorou et al., 2017](#)), and clearly such issues need to be acknowledged and addressed when groups are composed and facilitated to work.

We conclude by returning to the point at which the chapter started, viz. the changing landscape of policy – new curriculum – that has once more positioned teachers at the heart of the curriculum making process. While we welcome these trajectories, we also warn against the inherent dangers. These include a tendency to over-estimate the capacity of teachers to undertake full-scale curriculum making, particularly at times of economic austerity, and temptations to cut the resources required for such curriculum making. We especially point to risks of a “responsibilization” discourse in policy. While there has been, for some years, a strong emphasis in rhetoric about teacher importance, their agency, that teachers matter, etcetera, in *supra* (e.g., [OECD, 2005](#); [McKinsey and Co., 2007](#)) and national sites (e.g., [ICEA, 2018](#)), such rhetoric has easily slipped into scapegoating those same teachers, for example when PISA and TIMSS country results are published. Against this trend, we emphasize most strongly that it is teachers (as social actors) and enabling curriculum making contexts (as social practices) that matter. We theorize that teacher agency and curriculum making, as symbiotic concepts, enable each other; this highlights how teacher education, policy making, professional development and other related sites of social activity, should be informed by this reciprocal understanding.

Conceptualizing curriculum design

Defining related concepts as curriculum, curriculum design and curriculum development is an elusive activity. The concept of curriculum has been defined in literature in many ways, as exemplified during recent decades in three major curriculum handbooks (Connelly, 2008; Jackson, 1992; Wyse et al. 2016). Those usually long definitions often heavily depend on the specific contexts, roles and (ideological) perspectives of the authors (Jackson, 1992). We prefer a shorter, more open, neutral and flexible definition in order to recognize the complexity of the term (without premature closure to more narrow interpretations) and to facilitate wider use (Kridel, 2010). As curricula for educational settings are not given by nature but represent artifacts that are deliberately created by humans (Simon, 1996), it is obvious that they represent a typical *design* challenge, with many choices to be made. Simon (1996) defined design as “devising a course of action”, which also captures the essence of curriculum work. If one considers “learning” as the central action and overall aim in education, then the definition of curriculum as a *design for learning* suits well as a simple, open-ended, universal definition which allows for multiple specifications to various contexts and perspectives. The term design is also very appropriate as it refers to both “product” and “process” dimensions of curriculum (cf. Priestley and Biesta, 2013): curriculum artifacts (programmes and materials) as well as the series of acts that lead toward such artifacts and the way they are enacted in practice. The interpretation of curriculum as process underlines that curriculum is not a static document but may better be characterized as ongoing work-in-progress.

Traditionally, curriculum is primarily associated with the aims, content and organization of learning (Walker, 1990), but various authors (Klein, 1991; Van den Akker, 2003) have expanded this list of components to include: vision or rationale, goals and objectives, contents, materials and resources, learning activities, teaching strategies, assessment, grouping, time, and space. Especially when trying to redesign a curriculum and making it work in practice, it is wise to pay attention to the coherence of those components. The (normative) vision on the overarching, broader aims of learning and teaching serves as a central link, connecting all other curriculum components. A metaphor to illustrate this viewpoint is a spider web (Van den Akker, 2003; see Fig. 1), including guiding design questions for the many curriculum components. The curricular spider’s web points to both the flexibility and the vulnerability of curriculum, as every chain is as strong as its weakest element while all components are interrelated and interconnected.

Besides a visual representation of the challenging components, the curricular spider’s web can serve as an analytic tool to explore and clarify the discrepancies between the existing and desired curriculum as well as a design tool that assists developers in prioritizing next steps in the process of getting to a coherent curriculum.

In particular when “grand”, ambitious curriculum (re)design is at stake, one needs an underlying (or overarching) rationale (or vision), articulating the values and principles that offer a sense of direction and may help in choosing a position and striking a proper balance between the various broader aims of education: (i) creating a knowledge base for further learning and studies, (ii) preparing for the world of work, (iii) equipping for living in society, and (iv) stimulating personal development. (For some inspiration, including examples, for discourses about the curriculum rationale, see the OECD website on project “Education, 2030”). Obviously, priorities will vary over different stages of schooling and also depend on the dominant values in the specific educational context.

Fig. 1 The curricular spider's web.

If one considers curriculum design as a process, it may be seen as the core activity within a broader, usually iterative and lengthy process of curriculum development, that includes activities such as: analysis of needs and context (reviewing the current situation as well as forward-looking explorations of desirable options); formulating principles for the to-be-designed curriculum; drafting initial versions (prototypes) of (parts of) the new curriculum; seeking informative feedback about such drafts; constructing and trying-out more concrete curriculum parts, seeking a balance between ideals and practicality; exploring implementation chances; synthesizing parts into a coherent whole and fitting these into the broader picture. The curriculum development process usually involves many more (cyclic) interim steps and activities, also related to socio-political issues of decision-making. Eventually, often also challenges of scalability and sustainability become more prominent. Thus, curriculum development can be portrayed as an overall, iterative process of analyzing, designing and constructing, evaluating and implementing curriculum change. Curriculum design (in reality often redesign) cannot be easily isolated as a distinct phase – it is better to interpret it as an embedded activity within such a trajectory. We would argue that curriculum design regards the less routinized, intellectually most demanding tasks of imagining and creating new destinations and pathways of learning and teaching. As such it represents the heart and driving force of any ambitious curriculum development. In practice and over time, curriculum developers have followed various approaches and strategies to structure their design and development work. See section two for some elaboration on that.

However, before describing various approaches of curriculum design and development, it is clarifying to distinguish various curriculum levels or layers. For starters, it does make a difference whether the curriculum is meant for a specific school site or for a generic context. One may even elaborate such differences by identifying six possible levels (Van den Akker, 2003; Thijs and Van den Akker, 2009), including some examples of respective curricular “products”:

- Supra (inter-/transnational); e.g., the International Baccalaureate programmes, or the Common European Framework of Reference of Languages, or the curricular discussion documents or frameworks of international organizations as UNESCO or OECD.
- Macro (national, regional); e.g., Scotland’s “Curriculum for Excellence” or comparable documents of many other countries.
- Meso (school, institution); e.g., the school-wide curriculum of any specific educational organization
- Micro (classroom, group); e.g., lesson plans, curriculum materials, or textbooks for learning and teaching of specific parts of the curriculum.
- Nano (individual); e.g., the personal plan of studies of an individual student.

Thus, one should keep in mind that “the” curriculum does not exist. It is always necessary to specify the levels of curriculum one is referring to, in order to support clarity in communication. And, obviously, the level(s) of curriculum at stake will have implications for the most suitable development approach. Moreover, it is important to realize that curriculum change at scale will eventually have to relate to all those levels, thus implying much interaction between the various levels.

Another conceptually helpful distinction for understanding curriculum (design and development) is to differentiate between various curriculum representations (Goodlad and associates, 1979; Van den Akker, 2003):

- Visionary: The ideas, ideals and intentions for learning (and teaching), giving directions to or underpinning choices in the curriculum.
- Written: How the intentions are elaborated and specified in documents/materials.

- Perceived: How the intended curriculum is interpreted, in particular by teachers.
- Operational: How the curriculum is enacted in classroom practice.
- Experiential: How the curriculum is experienced, in particular by students.
- Learned: The learner outcomes of the enacted curriculum.

Often, there are tremendous gaps between the aspirations of the intended curriculum (visionary and written), the realities of the implemented curriculum (perceived and operational), and the results of the attained curriculum (experiential and learned). Hence, one could characterize the process of curriculum development as a comprehensive, systematic effort to transform ideas about desirable aims and contents for learning into documents and materials to stimulate instructional practices that foster learning activities and experiences leading toward intended learning outcomes. This systematic endeavor has usually many substantive, technical-professional and practical aspects. However, curriculum development processes also often carry many socio-political and contextual issues, with many uncertainties in making choices by many actors. Curriculum choices inevitably relate to (often conflicting) values and interests of various stakeholders and interest groups. Hence, curriculum development is sometimes even characterized as a war zone or battlefield (e.g., [Carnocahn, 1993](#)). Although tensions will always remain in the process of designing curricula, it does help if participants in curriculum decision making do have a clear understanding of the different curriculum perspectives in levels, representations, components, values and interests. Context always matters, and notably in curriculum approaches. It is important to always keep in mind that one size does not fit all. Moreover, while grand visions may have an inspiring and mobilizing effect, “big bang” approaches to curriculum change should be avoided. Instead, it makes sense to start with relatively small steps in designing and piloting new parts of an envisaged curriculum, departing from an analysis of the current situation in school practice and aiming at the *zone of proximal development* of those involved. Essentially, at this point, the idea of curricular design research becomes relevant as it may help to address uncertainties on various quality issues (which will be elaborated later on) and to improve quality.

Approaches to curriculum design

Curriculum design as process

As introduced in the previous section curriculum design is a core activity within the overall process of curriculum development. Curriculum development usually consists of various activities related to phases in the process: analysis, design, construction, evaluation and implementation (see for an overview [Gustafson and Branch, 2002](#)). While these phases may suggest that the process of curriculum development is linear, in reality the process is cyclic and iterative. In particular activities addressing evaluation and implementation of initial versions (prototypes of (parts of) the new curriculum) need to start already early in the process to prevent the development of curriculum products that may be valid from a scientific point of view but are not practical in the daily practice of teaching and learning.

Grounded in theoretical views about curriculum and curriculum design typically three approaches to curriculum design are described in the literature ([Marsh and Willis, 2007](#)): the instrumental approach ([Tyler, 1949](#)), the communicative approach ([Walker, 1971](#)) and the artistic approach ([Eisner, 1979](#)). More recently two other approaches are distinguished. The design of educational software applications used in software engineering resulted in the pragmatic approach ([Visscher-Voerman and Gustafson, 2004](#)). The last approach – curricular design research – emerged from the field of design research ([McKenney and Reeves, 2018](#); [Van den Akker and Nieveen, 2021](#)). **Table 1** presents an overview of the five approaches. After that we will discuss each approach.

Table 1 Curriculum design approaches: Overview.

	<i>Instrumental approach</i>	<i>Communicative approach</i>	<i>Artistic approach</i>	<i>Pragmatic approach</i>	<i>Curriculum design research approach</i>
<i>Characteristics of the approach</i>	Rational process	Intensive deliberation (especially at the start)	Creative reflection	Frequent evaluation of prototypes, user-centeredness	Interwoven design and research activities
<i>Design context</i>	Generic	Generic/specific	Specific	Generic	Generic/specific
<i>Focus of the process</i>	Coherent design	External consistency	Coherent design	Coherent design/external consistency	Coherent design/external consistency
<i>Teacher roles</i>	Implementer	Co-designer	Designer	Implementer/(Co-)designer	Implementer/(Co-)designer
<i>Conception of quality</i>	Design meets pre-specified requirements	Design meets requirements derived from broad consensus among stakeholders	Design meets the vision of the designer	Design meets requirements of the users	Design is relevant, justifiable, consistent, practical, effective, sustainable and scalable

Inspired by [Thijs and Van den Akker \(2009\)](#).

The instrumental approach

Tyler's seminal work "Basic principles on curriculum and instruction" (1949) is a classical example of the instrumental approach to curriculum design. Tyler articulated four questions to guide the curriculum designer: 1. In order to identify concrete learning objectives, what goals are pursued by this curriculum? 2. With which learning experiences can students achieve these objectives? 3. How to organize the learning experiences? 4. How to determine the effectiveness of the learning experiences? Answers to these questions can be found in several places such as the subject domains and the learning sciences (Sawyer, 2015). Curriculum development based on the instrumental approach puts an emphasis on analysis and design. Evaluation and implementation are – when they occur – conducted at the end of the process for summative purposes. The instrumental approach is rooted in prescriptive theories in searching for heuristics that guide a design process leading to curricula of the highest quality (Marsh and Willis, 2007). Such an approach strives after a design that is coherent, see the spider web introduced above (Van den Akker, 2003).

The main elements of the instrumental approach are often used in large-scale curriculum development processes with a generic focus, but increasingly also in school-based curriculum development processes. While in the instrumental approach teachers are above all seen as implementers of a high quality curriculum, increasingly teacher designers use elements of this approach when developing curriculum (McKenney et al., 2015; Pieters et al., 2019).

The communicative approach

While the instrumental approach strives after a coherent design, the communicative approach emphasizes the importance of shared understanding and creating ownership among different stakeholders for the process and the product of curriculum development, Kessels and Plomp (1999) refer to this as external consistency. The communicative approach is rooted in descriptive theories, which study what people actually do and how design decisions are taken. Walker's (1971) deliberative approach is a typical example. In this view, curriculum design is above all a process of negotiation among key stakeholders such as policy makers, teachers and scientists, who each bring their own knowledge, experiences, beliefs and values to the curriculum design process. That is why the deliberative approach starts with an open platform of ideas to discuss with major stakeholders the intended curriculum. An open discussion contributes to consensus about the rationale for the design and a shared understanding of the task. This phase is followed by deliberations about possible alternatives and their consequences leading to a decision about the most promising alternative. Although these two phases are distinguished in reality there is not a strict boundary. The emphasis of the approach is on building consensus about the curriculum at the start of the process, and on needs and context information during deliberations of alternatives. Little attention is paid to evaluation and implementation of the design. The communicative approach is used in large-scale generic curriculum design as well as in school-based curriculum design. Teachers are seen as major stakeholders in the design process. In large-scale generic design processes, they are frequently invited as co-designer for parts of the process (Turcotte et al. 2010), while in school-based curriculum design, teachers, often collaborating in teams, design for their own school or subject domain (Pieters et al., 2019).

The artistic approach

According to Eisner (1979), the process of curriculum design is similar to the process of creating art. Eisner sees curriculum design as a process of sense making based on the expertise and experience of the connoisseur. As such the artistic approach is rooted in the theory of situated cognition (Greeno, 2011). It is a social practice that takes place in a specific context and culture. Curriculum design is a process of construction and reconstruction of teachers, who uses their "wisdom of practice" (Shulman, 1986) to fully understand and enact the curriculum. It is often an intuitive and implicit process, and not based on an explicit course of action. Because means and ends are interdependent, the process of curriculum design is not linear but open ended. However, like Tyler, Eisner agrees that the curriculum elements, as visualized in the spider web, need to be addressed in relation to each other for a coherent design. The artistic approach is applied in curriculum design processes at the level of classrooms and schools. The teacher as designer of curriculum needs some curriculum design expertise to be able to arrive at a more systematic approach to realize a coherent design (Huizinga et al. 2014; McKenney et al., 2015).

The pragmatic approach

Due to the increasing use of educational software in education the pragmatic approach, derived from software engineering, is gaining ground in curriculum design (e.g., Nieveen, 1999; Visscher-Voerman and Gustafson, 2004). The pragmatic approach is highly iterative, because of the formative evaluation of successive prototypes. Successive prototypes provide concrete pictures of the intended curriculum already from an early stage of the design process. Formative evaluation leads to revision suggestions and adaptation of the evolving ideas that underpin the product. The user-centeredness of this approach leads to more intensive discussions with the end-users about the requirements of the product, provides better opportunities to negotiate and justify design ideas, increases chances for user-commitment and ownership of the final deliverable and moreover prevents curriculum developers from a tendency to "design for themselves". Each cycle represents the evolution of intentions of the final deliverable. End users, often

teachers and their students (and not their representatives or school leaders), are actively involved in the formative evaluation of the prototypes (Tripp and Bichelmeyer, 1990). The pragmatic approach leads to a final product that works in practice and is considered practical by its users (Visscher-Voerman and Gustafson, 2004).

Curricular design research approach

Curricular design research (CDR) can be conceived as a special form of educational design research (McKenney and Reeves, 2018; Van den Akker and Nieveen, 2021). Characteristic for this type of research is the close interaction between design, its iterative and cyclic nature, and targeted research activities to inform the design process. CDR builds on ideas of the instrumental, the communicative and the pragmatic approach: a systematic process that leads to coherent high quality design (instrumental approach); attention for shared understanding of stakeholders (communicative approach) and (rapid) prototyping with formative evaluation as core activity in the design process (pragmatic approach). More prominent than in the other approaches is the important role of research in all phases of the process with the aim to contribute to valid, practical, effective and sustainable curricular artifacts and practices. Moreover, CDR produces knowledge about curriculum design and development in the form of design principles that are ecologically valid and may guide future curriculum design in similar contexts.

CDR has been successfully applied in large-scale curriculum development and in school-specific curriculum development processes. In the latter case teachers often collaborate in teams. The active involvement of participants (e.g. teachers, school leaders) in the process contributes to their professional development.

To ensure that the curriculum that results from CDR is of high quality, the following criteria are formulated (see Van den Akker and Nieveen, 2021):

- **Relevance:** Is there a clear and shared rationale for the new curriculum?
- **Justification:** Is the curriculum supported by a credible knowledge base?
- **Consistency:** Are the various curriculum components (see spider's web) well aligned?
- **Practicality:** Is the curriculum feasible in practice (especially for teachers and learners)?
- **Effectiveness:** Does the curriculum result in the intended learner outcomes?
- **Sustainability:** Is the curriculum change successful in traveling over time?

And in case of large-scale development processes also.

- **Scalability:** Can the curriculum operate across various contexts?

Apart from an extensive preliminary research at the start and the implementation and scaling at the end, the development process entails a cyclical process of analysis, design/construction, and evaluation as a phase in the middle. Working on the relevance and justification are important criteria in the preliminary research phase. Here, stakeholder consultation, the analysis of the current practice and a review of research are important activities. During the cyclical analysis, design and evaluation phase in the middle, the focus is mainly on consistency and practicality. Typical activities during this phase are the formative evaluation of prototypes through walk-throughs, micro-evaluations and try-outs. During the implementation and scaling phase research activities focus on determining effectiveness, sustainability and scalability. Effectiveness can be found through empirical testing. The sustainability and scalability of the design can be determined through case studies and surveys.

Actors in curriculum design

Curriculum policy and actors

Starting from the idea that curricular documents are to be found at various levels in the educational system (supra, macro, meso, micro and nano; see earlier in this contribution) and that large-scale curriculum change will have to relate to decisions at all those levels, it is central to note that curriculum development is the responsibility of many different players in the educational field (illustrated with a system web, Fig. 2), and many more actors are usually involved in the development process itself. The nature of their involvement and responsibilities depend on the curriculum policy of a country.

In countries with a centralized curriculum policy, the curriculum at the macro level is typically highly specified and prescriptive from the idea that the curriculum change in the classroom should closely correspond to/align with the prescribed intentions. Here the curriculum policy starts from a "fidelity" approach (Fullan and Pomfret, 1977) that directs teachers to select and use particular lesson units in specified ways. This approach aims at uniformity, requiring that all schools teach the same topics in similar ways, in which the room for site-specific curricular choices is restricted.

In countries with a decentralized curriculum policy, the curriculum at the macro level leaves ample room for teachers and students to make local curricular decisions, based on for instance what happens in the classroom or in the context of the school. This means that next to their teaching duties, teachers will be involved in the design of a school-based curriculum. At the heart of this "mutual adaptation" approach is trusting schools and teachers to make site-specific interpretations of curriculum guidelines (Hopkins, 2001). Adjustments and insights of teachers and other stakeholders are also used to feed changes in the curriculum at the macro level in order to improve, for instance, its relevance and practicality.

Fig. 2 Curriculum system web (Nieveen, van den Akker and Resink, 2010).

As was already stated, the nature of the involvement and responsibilities of the many actors in the educational field depend on the curriculum policy of a country. In countries with centralized policies, the actors in the system web have a role in directing and standardizing the curriculum implementation in the classroom. This happens usually at great cost to professionalism and motivation of teachers (cf. Hargreaves and Shirley, 2009). In countries with a decentralized approach, the role of the actors in the system web is much more diffuse. In these countries the needs and wishes of the schools, teachers and learners are steering their work. Where schools and teachers are in charge of the actual implementation of the curriculum in practice, all actions taken by others in the system web (policy makers, school boards, support agencies, test developers, textbook developers, pre- and in-service education, inspectorate, and so on) can to be considered as implementation encouragement (Nieveen et al., 2014).

Role of networks

Scaling of curriculum change that has been initiated at the macro level is a serious challenge for many countries (Fullan, 2008) and related to that countries show a difficulty in striking a good balance between both (decentralized and centralized) positions. Both prescriptive and more flexible models have their advantages and disadvantages (Fullan, 2008; Hargreaves, 2003). In short, the dilemma is that prescriptive models obtain better short-term results but usually lack sustainable change, while flexible models usually last longer but often lack focus (Fullan, 2008). Flexible models tend to last longer because at their heart is trust in schools and teachers leading the curriculum renewal (Hopkins, 2001). The latter is generally perceived as a prerequisite for securing sustainable change (Hargreaves and Shirley, 2009). At the same time, prescriptive models also need deliberately measured doses of pressure and support to put change into practice.

Concerning curriculum change, all dimensions of scale as elaborated by Coburn (2003) are at stake: spread over more people and organizations; shift in ownership from original source to other people and contexts; depth in the practice of teaching and learning in schools; sustainability over longer periods of time. To address these challenges, more mixed collaboration approaches between teachers, school leaders, teacher educators, textbook developers, assessment developers, researchers and the like, e.g. in networked improvement communities (Bryk et al., 2015), seem to be promising for common professional capacity building as well as gradually coming to scale. These kind of networks fit best with a mutual adaptation philosophy with sufficient space for and active encouragement of context-specific choices for local communities, parents, schools, teachers, and students. A clear example of such a localization approach (within the boundaries of the national framework) can be found in Finland (Halinen and Holappa, 2013), where local communities are expected and supported to make, translate, and add their own curriculum choices, together with the schools in that particular community. This also requires that teachers, being the key players in curriculum change, have not only an appropriate degree of professional autonomy in the pedagogical and instructional domain, but also have a sufficient degree of curricular capacity to recognize and utilize the potential to cooperate in designing their common school-based curriculum. Such curricular-capacity building of teachers individually and in teams, while also including school leaders, should be an important aim of professional development strategies (Huizinga et al., 2014).

In order to bridge the gap between the work of individual teachers (within their own subjects and classrooms) and school-wide curriculum renewal aspirations, teacher design teams are to be of help (cf. Handelzalts et al., 2019; Lieberman and Miller, 2004; McLaughlin and Talbert, 2001). These small networks of teachers from adjacent subjects center their work on students, share their responsibilities, work together on their common curriculum, make meaningful connections between topics that are usually addressed in different subject areas, reflect on and learn from their experiences (at the individual, group and school level). Although

all teachers need to be involved, one way or another, in some parts of the process of developing the new curriculum and feel that they have collective responsibility. Skilbeck (1998) points out that as talents and interests vary, and as there are different kinds of development tasks to perform, matching procedures are inevitable, meaning that not all teachers need to be actively involved in all curriculum development tasks.

Ultimate success, with deep curriculum change in classrooms, where teachers use new materials, engage in new teaching practices and incorporate new beliefs, will require lots of investments in bottom-up initiatives (Fullan, 2016). Teacher design teams constitute a promising vehicle for this kind of school-based curriculum development, potentially addressing all four of Coburn's dimensions. This implies that these teams have sufficient facilities (in particular development time) and access to adaptable exemplifications (e.g., educative lesson materials; digital portals). Such scenarios and examples can be the result of the earlier mentioned work of heterogeneous networked improvement communities.

Moreover, schools and teacher teams are in need of a clear curriculum at the meso level in order to bridge the curricular aims of the school and the instructional decisions at the classroom level. As long as this curriculum at the school level remains a "black box", it serves a situation where "anything goes," which in the end merely leads to incoherent situations for teachers and learners (Nieveen et al., 2010). Schools need curricular leaders who feel and act responsibly with the curriculum and who encourage others to strive for decisions that fit the curriculum choices at the other levels. Again, professional development of teachers as cooperative designers requires time facilities, a cooperative culture and energizing distributed leadership.

Of course, the differences between primary and secondary schools need to be taken in account. In secondary schools, the role of subject matter teachers is more dominant, asking for other collaboration patterns than in primary schools, where usually more generic teachers are responsible for a wide range of domains. However, regardless the specific education sector, the strong point of combining teacher design teams, the role of curriculum leaders in the school and networked improvement communities is that they expand the basic repertoire of individual teachers from designing lessons for their own classes to more collaborative, curriculum-oriented and research-supported patterns which is beneficial for the professional development of all involved and the quality of the curriculum change at hand.

Introduction

The focus of this chapter is on learning for vocations, including both learning *for* practice and learning *in* vocational practice, and learning environments that afford such learning. Learning *for* vocational practice pertains to learning in the context of vocational education.¹ Learning *in* vocational practice concerns learning in the context of continuing education, further professional development, and lifelong learning. Learning for vocations, whether *in* or *for* vocational practice, involves the individual process of developing a vocation in terms of competencies of and being a professional. It entails preparing for participating in vocational practice and/or remaining qualified to contribute in work in a rapidly changing society. Learning for both initially becoming a professional, as well as learning for further professionalization demands from learners that they participate in communities of practice related to work, that they cooperate with other professionals from both comparable and dissimilar backgrounds, and that they continue to develop both themselves and the professional community they work in. Learning for vocations occurs within the context of formal education and in the context of lifelong learning. In line with Billett (2011), we use the term vocational education for all learning for vocations, whether low skilled or high skilled (such as physiotherapy or accounting), primarily aimed to prepare and qualify for work. Vocational education serves many purposes, mainly related to vocational education being a means for individuals to get or remain qualified for occupations throughout their (working) life (Billett, 2011). A large variety of learners is involved in learning for vocations, ranging from adolescents and young people to adults in different stages of their lives and careers. And while some learning for vocations is considered prestigious (such as learning to become a medical doctor), other trajectories are set up for young people to overcome disadvantages on the labor market (Behle, 2017), to help learners to get qualified despite prior poor school performance (Chan, 2013), or to handle unemployment and shortages of skilled labor (Ferm et al., 2018). While such learning environments are arranged in educational programs governed by different regulations, norms, and enrollment procedures and are situated in various social-cultural settings and conditions, there are also similarities and insights with respect to the learning processes and activities that can be instructive for investigating and eliciting learning in these differing settings.

The question of how (future) professionals learn and how this learning can be supported is a pressing and central issue for educators, whether in school or at the workplace (De Bruijn, 2012). It is related to the complex relation between (the individual learners' perception of) learning and the learning environments eliciting this learning. Evidence shows that learning is embedded in and results from social practice. Social practice serves as learning environment and can also be intentional (i.e. designed) (Entwistle and Petersen, 2004; Tynjälä et al., 2021). The assumption is that the way (future) professionals learn is—at least in part—afforded by the learning environments they are part of and the interactions with significant others while active in these learning environments (Koenen et al., 2015; Bouw et al., 2021a).

We believe that learning of individual learners is intertwined in social practice. Hence, in this chapter we use the body of knowledge in which learning *for* and *in* vocational practice is conceptualized from a socio-cultural perspective for our analyses (Hökkä

¹(Upper) Secondary Vocational Education (ISCED/EQF 3-4) and Higher Education (ISCED/EQF 5-7) are within the scope of this chapter.

et al., 2020). From this socio-cultural view, learning is perceived as increasing participation in and contribution to a professional community, which may emanate in developing occupational roles and behaviors, vocational knowledge, and a vocational identity (see e.g. Lave and Wenger, 1991). Learning is situated: it is viewed as growing engagement in and belonging to a vocation, i.e. a professional community of practice (Chan, 2015). Knowledge and actions are developed simultaneously in such Communities of Practice (CoP) (Hodkinson et al., 2008). In CoPs, learning may result in changes pertaining to the learners themselves (e.g. new insights, newly developed skills or actions) or changes to the CoP in question, also affecting the more experienced professionals in it (Engeström, 2001; Smith, 2012). The concept of boundary crossing plays an important role: boundaries are “socio-cultural differences leading to discontinuity in action or interaction” (Akkerman and Bakker, 2011, p. 133). Such differences between domains or communities and experiences of discontinuity may elicit learning when part of a learning environment.

In a recent systematic review of literature on learning for and in vocational practice (Koopman et al., in preparation), we focused on the way in which (future) professionals’ learning processes and accompanying learning activities are conceptualized and empirically studied. In this review, we made a distinction between which *learning processes* are defined and which *learning activities* are described (see Table 1). Learning processes are defined as configurations of several learning activities. Such processes take time and lead to change (e.g. in knowledge, actions, or attitudes). Learning activities are defined as actions (doing or thinking) related to task performance (e.g. cooking, thinking aloud, having a conversation) that take place at a particular point in time.

In this chapter, we look at learning processes and learning activities in the reviewed literature in relation to the learning environments which may elicit such learning processes and activities as described in this literature.

Taking a broad view on learning environments, these are considered as “both the socio-cultural setting and the physical/digital setting in which learners perform their tasks (Carvalho and Goodyear, 2018; Zitter and Hoeve, 2012)” (Bouw et al., 2021a, p. 489). Learning can be enhanced by the interplay between interactions and affordances. Interaction involves all interactions between (future) professionals and “significant others,” such as teachers, supervisors, peers, experienced professionals from the workplace, clients, etc. (Ceelen et al., 2019). Affordances refer to the perceived elements of environments that may elicit learning processes and activities, for example, tasks, roles, (professional) tools and objects, digital environments, physical locations and spaces at school and/or at the workplace, and timeframes (e.g. deadlines, sequences, and schedules) (Bouw et al., 2021a). Both interactions and affordances may arise from intentionally shaping the so-called *designable elements* of an environment and as such aim to enhance learning. We refer to these environments as learning environments. It should be noted that the learning processes and activities themselves cannot be designed, but the epistemic, physical, and social elements (i.e. the designable elements) of the environment in which this learning unfolds can be intentionally designed (Carvalho and Goodyear, 2018). That is, in learning environments interaction and learning processes and activities are emergent and the designable elements are there to elicit these, which consequently may lead to the intended (learning) outcomes. In this way learning environments can elicit or support certain learning processes or activities to be carried out by learners (see Fig. 1).

The following designable elements can be distinguished (Bouw et al., 2021a,b):

- *Epistemic elements*: tasks and assignments that represent ways of knowing—including skills and attitudes—that are seen as worthwhile in the professional domain(s) in question. Moreover, these elements are related to how the ways of knowing can best be presented and structured to elicit learning. Specifically when learning for and in vocational practice, this involves determining which work practices are suited for (the intended) learning and what kind of vocational tasks learners are supposed to engage in while active in these work practices;
- *Spatial elements*: the locations and spaces (both physical and digital) in which learning takes place. Locations/spaces are at school, at different workplaces, or at third places (neither school, nor work) which are relevant for the professional domain (for example, a specific area or neighborhood);
- *Instrumental elements*: the instruments, tools, objects, and artifacts needed for the (intended) learning processes and activities. Some are more oriented toward schools, while others are necessary to perform the vocational tasks in question (see epistemic elements). Specifically when learning for and in vocational practice, artifacts that facilitate the interaction between school and work, i.e. boundary objects, are likely. Smartly chosen professional artifacts can function as boundary objects;
- *Social elements*: the actors involved in a learning environment, the roles these actors fulfill, how they are grouped and how tasks are divided between them. When learning for and in vocational practice, actors from both school and work may be involved, fulfilling both education roles (e.g. learner, coach, or assessor) and roles related to the relevant professional domain (e.g. junior or senior colleague and managerial roles). One person can fulfill several roles at the same time, e.g. a students can be “learner,” junior colleague in relation to a seasoned professional, and senior colleague in relation to an even more junior peer. Roles can also be fulfilled by different persons concerned, e.g. a teacher can also explicitly fulfill the role of senior colleague.

Table 1 Distinction between learning processes and learning activities.

	<i>Learning processes</i>	<i>Learning activities</i>
Definition	Configuration of several learning activities Leads to changes in knowledge, actions or attitudes	Actions (doing or thinking) related to task performance e.g. thinking aloud, having a conversation
Timeframe	Longer time span	Particular point in time

Fig. 1 Designable elements of learning environments.

- *Temporal elements*: these elements are included to clarify the importance of affordances related to time. Designable temporal elements are, for example, work pace (e.g. available amount of time-on-task, deadlines, time pressure), and overall intensity and timespan. When learning for and in vocational practice, opportunities to interrupt the work process can be designed, in order to slow down, accelerate, or pause for educational purposes. Temporal elements also include sequencing of tasks as described under epistemic elements and the position of a task in overall learning trajectories.

When consistently designed for eliciting specific intended learning processes and activities, the epistemic, spatial, instrumental, social, and temporal elements, may afford this desired learning.

The main question we answer in this chapter is: *Which designable elements can be identified in the social contexts where learning for and in vocational practice occurs?* To answer this question, we make use of the results of the systematic literature review, searching for the designable elements mentioned in the included studies. As such, the chapter intends to contribute to the knowledge base on the relation between (intended) learning processes and activities and designing for learning in vocational education. It may also provide concrete directions for educational designers and educators on how to support (future) professionals' learning for and in vocational practice.

Review process

We conducted a systematic review of literature on learning processes, and learning activities related to learning *for* and *in* vocational practice (Koopman et al., in preparation). We used an interpretative approach to analyze the included studies in order to broaden our understanding of these learning processes (Dixon-Woods et al., 2004). We conducted the search in ERIC, PsychInfo, and Web of Science (period 2009–2020). Four sets of search terms were used simultaneously to search the title, keywords, and abstract of publications:

- Set 1: learn* OR develop* OR becom* AND
- Set 2: knowledge* OR skill* OR attitude* OR identit* OR competenc* OR member* OR activit* OR practice OR expert* AND
- Set 3: vocational OR occupational AND
- Set 4: process*

This resulted in 944 unique hits. From these hits, we made a selection based on reading the title, keywords, and abstract using the following inclusion criteria for an article to be selected for further scrutiny: (a) the article had to describe learning processes (i.e. there is a learner; the research design and method leads to data on learning processes; the results and/or conclusions are about learning processes), (b) the article had to include empirical research (i.e. data have been used; data describe learning sufficiently concrete), and (c) the article had to focus on learning for vocations in the context of initial *vocational education* or *non-formal education* (instead of working communities without the intention to learn). 35 primary studies were included, 30 of which described student learning from a socio-cultural perspective; the five other studies described learning from cognitivist or constructivist perspectives. These 30 studies described learning for and in vocational practice in Australia, Brunei, Canada, Denmark, the Netherlands, New Zealand, Norway, South Africa, Sweden, the United Kingdom, and the United States. Most studies reported on learning for and in vocational practice organized via secondary vocational education or higher education ($n = 23$); the other seven studies reported on learning in continuing education (learning at work).

In this chapter, we limited our analyses to the dominant view of socio-cultural learning theory. Because of this focus, we were able to zoom in on the social practice in which learning for vocations is embedded and identify designable elements that might

afford such learning. For our analyses, we used the frame of designable elements of learning environments as described by Bouw et al. (2021a,b), i.e. epistemic, spatial, instrumental, social, and temporal elements as explained above.

Results

Learning for and in vocational practice involves participating in vocational practice, development of the knowledge that is relevant for practising a vocation, and development of one's identity as a (future) professional. In the 30 articles included, these three specific foci of learning could be identified; formulated more precisely (a) learning how to act in vocational practice, (b) developing vocational knowledge, and (c) developing a vocational identity. We used these three foci of learning to guide our analyses of which designable elements were mentioned in the included studies and how these elements were described to afford learning. In some of the articles one or two of these foci were recognizable. And, in case of two foci, all kinds of combinations existed, for example a focus on both acting in vocational practice and identity development or a focus on both acting in vocational practice and knowledge development. In other articles all three foci seemed present. From a socio-cultural view on learning these three foci are related and can be seen as inseparable (Colley et al., 2003). As meaning-making and sense-making are embedded in social practice (Bijlsma et al., 2016), acting in vocational practice will be reflected in both knowledge development and identity formation. Together these three foci can be considered to form the core of what it means to become a professional in a certain field (see e.g. Ord and Nuttall, 2016; Stets and Burke, 2000; Wallin et al., 2019). For analytical purposes, in the next sections the learning processes and activities are described in more detail per focus, zooming in on designable elements of learning environments we found in the reviewed literature that can afford learning.

Learning how to act in vocational practice

Learning processes and activities

Participation is typical for the way in which learning how to act in vocational practice is perceived (Bijlsma et al., 2016). The transition from peripheral to full participation in a CoP or activity system is key. Students' situated *learning processes* can be characterized by socialization, experiential learning, and increasing commitment and independence (Poortman et al., 2011; Pridham et al., 2012; Reegård, 2015). In some studies, learning processes related to boundary crossing, characterized by reflection and transformation, are added (Akkerman and Bakker, 2012). *Learning activities* of students can be characterized by doing (all kinds of work-related tasks), exerting agency of their own learning (e.g. taking initiative, asking for demonstrations or feedback, having discussions), thinking (in order to support development of acting), and contributing to building a CoP (Ferm et al., 2018; Chan, 2015; Jonasson, 2015; Pridham et al., 2012). Learning activities are typically combinations of actions and interactions, with students negotiating about their engagement in activity (Smith, 2012). For example, during workplace learning future industrial workers learn through doing everyday work in industry, paying attention to what happens in the workplace, and having others demonstrate tasks (Ferm et al., 2018). They are invited to participate in activities by their co-workers and hence become engaged in those activities, resulting in them learning the informal rules and ways of working of a specific workplace.

Designable elements affording learning how to act in vocational practice

Epistemic elements

Tasks that may elicit learning how to act in vocational practice are designed with a focus on acting and doing the work relevant to a profession. In many of the included studies, learning while doing occupational tasks is somehow part of the overall learning trajectory that results in formal qualification. Learning by working on actual occupational tasks can afford socialization and experiential learning (Chan, 2013; Lie et al., 2016). The participation of students in a CoP can be encouraged via a combination of increasingly difficult tasks and fading support (Chan, 2015). Sometimes, doing work tasks is combined with supporting assignments or projects (Knightbridge, 2014). In such cases, a more explicit link is designed between school-based and work-based learning. Experiences from the work tasks can be discussed, which—in some cases—seems to support meaning-making and understanding (Ferm et al., 2018; Johansson et al., 2019). In other cases, theory-oriented courses are provided on work-oriented content, which can result in students' experiencing boundaries or discrepancies between school and work. These experienced boundaries can also be discussed and can thus instigate learning (Akkerman and Bakker, 2012; Bakker and Akkerman, 2014).

Spatial elements

The physical environment in which (future) professionals learn how to act is often a real work setting, such as a shop, factory, bakery, or fitness facility (e.g. Chan, 2013; Ferm et al., 2018; Poortman et al., 2011). In case of learning *for* vocational practice in formal vocational education, this often takes place in the form of apprenticeships, internships, or placements in (future) occupational workplaces. In some studies, learning how to act as a professional is attempted to be afforded in a school-based setting, which can be characterized by in-school work settings similar to vocational practice (for example, a school-based mini enterprise or an in-school kitchen with restaurant) (Heusdens et al., 2019). In case of learning *in* vocational practice, it generally involves learning on the job.

Instrumental elements

Regarding learning how to act in vocational practice, a variety of tools, objects, and artifacts is described. These instrumental elements are generally related to and typical for the vocational tasks the (future) professional has to become experienced in. Examples of such instruments are lesson plans provided by the university that support the development of student teachers toward becoming a teacher (Goh, 2015); ingredients and equipment in a bakery or kitchen that enable learning on the job by bakers-in-training (Chan, 2013); and lab materials, machines, and protocols in laboratory education elicit acting (and thinking) similar to vocational practice (Bakker and Akkerman, 2014). Sometimes, such instrumental elements may serve as boundary objects that enable learning how to act. In case of learning how to be a security officer, for example, a uniform may serve as a transformational artifact eliciting discussions about the contradiction between (personal) threats and protection (of others) inherent to the work (Johansson et al., 2019). The discussion of the purpose and meaning of wearing uniforms, may support security officers-in-training in prioritizing their future actions and in becoming familiar with the norms and standards of the profession.

Social elements

Regarding social elements that encourage learning how to act in vocational practice, the importance of interaction between learners themselves and between learners and supervisors, mentors, or (future) colleagues is quite clear. (Future) professionals form communities of practice or communities of learners, do group assignments, have discussions, consider each other as experts or sources of knowledge, and are thus able to help each other (Pridham et al., 2012). Settings in which several learners meet, facilitate conversations in which learners make their implicit experiences more explicit, which—in turn—supports their thinking about their actions (Johansson et al., 2019). Learners are also supported by co-workers (who sometimes have a formal role as supervisor or mentor). In their role of junior colleague, learners tend to ask these more experienced professionals for demonstrations of vocational actions which they can observe (Pridham et al., 2012). In some studies, co-workers are described as being brokers who represent a certain professional domain and who make students aware of the discrepancies between professional communities they are already familiar with (e.g. a former job) and new professional communities (Andersson and Köpsén, 2019). A particular role is described for educators in school or at the workplace: they stimulate acting as professional by inviting to participate, encouraging, providing feedback, and acknowledging (growing) competence (Emad and Roth, 2016; Johansson et al., 2019). In some cases, learners are described to mirror this guidance by exerting agency over their own learning, taking up responsibility, and doing increasingly difficult tasks (Goh, 2015; Reegård, 2015).

Temporal elements

Affordances for learning how to act in vocational practice in the sequence of an overall learning trajectory are often strictly timeboxed, with separate timeboxes related to learning at work and separate timeboxes related to learning at school. In other words, learning how to act in vocational practice is clearly divided in timeframe and planning between settings at school or at the workplace. In the included literature, learning how to act is often described from the perspective of learning at work (e.g. Bisholt, 2012; Chan, 2013; Smith, 2012). Some other studies report slightly more fluid presence of the temporal elements. In these studies, learning at work is interspersed with “come back to school time” often dedicated to reflection on work experiences (Akkerman and Bakker, 2012; Johansson et al., 2019; Ferm et al., 2018). Learning at school and learning at work can even occur more or less simultaneously, in hybrid settings, but such settings are hardly described in the reviewed literature.

Developing vocational knowledge

Learning processes and activities

Development of vocational knowledge—like learning how to act in vocational practice—is closely related to participation (Chan, 2013; Heusdens et al., 2019). Important *learning processes* specifically related to developing vocational knowledge are meaning-making and sense-making. Meaning-making pertains acquiring meaning through interactions with other (prospective) practitioners of the vocation, for example via interpreting collective knowledge and concretizing personal knowledge (e.g. becoming acquainted with collective meanings, reflection on concepts, values and beliefs, or “vocationalizing” concepts) (Bijlsma et al., 2016). Sense-making is related to making knowledge personal and, through that, developing new collective knowledge (Heusdens et al., 2019; Johansson et al., 2019). It involves perspective taking, contextualizing, interpreting and integrating collective knowledge, and personalizing vocational knowledge. *Learning activities* related to developing vocational knowledge can be characterized by the link between thinking and acting as well. Granting meaning to concepts is typical, for example, and occurs by means of using and refining concepts in or for particular work tasks (see e.g. Bijlsma et al., 2016).

Designable elements affording developing vocational knowledge

Epistemic elements

Like learning how to act in vocational practice, developing vocational knowledge in many cases involves or is closely related to learning while doing occupational tasks. From this participation in work, development of know-how or vocational knowledge can emerge (Chan, 2013; Heusdens et al., 2016, 2019). Epistemic elements that may afford vocational knowledge development include consecutive tasks that seem to be created or provided in such a manner that they become increasingly difficult for learners. Moreover, intentionally designing difficult tasks seems to play a role in developing vocational knowledge (Jonasson, 2015). In the

study of Jonasson (2015), for example, learners in culinary education are confronted with deliberately complicated tasks that demand improvisation and are prone to mistakes. These tasks are a starting point for interaction among learners or between learners and educators, resulting in (future) professionals extending their repertoire and their knowledge about cooking, improving the techniques and procedures they use, and strengthening their ability to combine work tasks under time pressure.

Spatial elements

Though developing vocational knowledge is likely to take place during workplace learning, affordances for learning processes and activities related to knowledge development often seem to be school-based (Heusdens et al., 2019; Jonasson, 2015; Pridham et al., 2012). These spatial elements can sometimes be characterized by simulation of a real-life work setting (e.g. a catering company within a school).

Instrumental elements

An example of developing vocational knowledge while acting at a real workplace can be found in the work of Johansson et al. (2019), who describe shoemakers-in-training developing embodied knowledge during operating machines, while working with leather and feeling how the leather behaves. Several tools, objects, and artifacts play a role in eliciting development of vocational knowledge. Because of the close relation between acting and knowing, these instrumental elements are overlapping with the elements described in **Designable elements affording learning how to act in vocational practice** section. Additionally, the studies in which learning for the development of vocational knowledge is described, instrumental elements such as books and literature are mentioned explicitly (e.g. Holmgren et al., 2017).

Social elements

Regarding social elements that encourage the development of vocational knowledge, a combination of observing (peers, co-workers), interacting, posing questions, and having discussions seems to support learning (Bakker and Akkerman, 2014; Chan, 2013; Holmgren et al., 2017; Johansson et al., 2019). Together, and in close relation to vocational actions, these strategies seem to help (future) professionals in sharing and co-constructing knowledge via, for example, reasoning, articulation and elaboration of concepts (Bakker and Akkerman, 2014; Heusdens et al., 2019; Holmgren et al., 2017). For example, students that learn how to cook, develop knowledge by connecting concepts (e.g. the concept of Julienne cut) to their vocational activities (e.g. cutting a hot pepper) or by both interpreting and articulating what they do (e.g. skinning a tomato using first boiling and then iced water; Heusdens et al., 2019). Hence, designable elements which afford making knowledge explicit are an important way to give shape to the social elements of learning environments in order to make knowledge development more likely. Educators, in the role of senior colleague, may also fulfill a prominent role in this; they can support learners in developing vocational knowledge by helping them in conceptualizing and concretizing knowledge (Heusdens et al., 2019). Conceptualizing involves understanding what a concept means in a specific situation in relation to the meaning of other concepts. Concretizing involves understanding the use of concepts in a situation and interpreting that situation to be able to transform and use concepts appropriately. Both are complex processes, which can be supported by elaboration and questions from a teacher in the role of senior colleague. A teacher in the role of expert can also be seen as a source of knowledge and may give direct support in knowledge development (for example related to articulating knowledge and helping students reason), but also more indirect support (for example in the form of the subdivision of tasks and encouraging learners).

Temporal elements

At the level of distinct learning processes and activities, in the aforementioned simulated settings are explicitly designed to make pausing or interrupting ongoing work processes for instructional purposes possible (Bouw et al., 2021a), which may support vocational knowledge development. At the level of an overall learning trajectory, the sequence learners are involved in related to developing vocational knowledge seems to be characterized by alternation between school-based learning, workplace learning in the form of apprenticeships, and/or shorter workplace visits (e.g. Andersson and Köpsén, 2019; Chan, 2013; Johansson et al., 2019). As stated earlier, the actual development of vocational knowledge, or at least making this knowledge explicit, seems to occur relatively frequently within the school setting.

Developing a vocational identity

Learning processes and activities

Learning in terms of the development of a vocational identity, is often described in terms of “becoming” (becoming a baker, shoemaker, teacher, occupational therapist, etc.) (Chan, 2013, 2019). This involves *learning processes* that can be characterized by going through the phases of belonging, becoming, and being (Chan, 2013). This process starts with the feeling of fitting in a certain professional world, followed by becoming competent in the professional role that is demanded, and finally complete identification with the profession (to sometimes even seeing the profession as a calling) (Chan, 2019). In other words, it involves a process of positioning oneself toward the profession that is learned and transformation of an identity via participation in the professional community. In some publications, a process of identity work, characterized by integrating or combining identity positions and thus transforming identity, is described (Akkerman and Bakker, 2012). *Learning activities* related to the development of a vocational identity include creating opportunities to learn (by taking initiatives) and contributing to building a CoP (with a focus on sharing

motives and stories, discussing occupational roles, rules, norms, and values) (Ferm et al., 2018; Johansson et al., 2019; Pridham et al., 2012). In some studies learning activities are described that involve negotiations, particularly about the way the learner is engaged in a professional community and personal versus occupational norms (Smith, 2012). For example, based on his prior experiences a fire fighter negotiates regarding the way he personally likes to prepare and test his breathing apparatus compared to official protocol, enabling him to work in a more safe and quick way. As such he negotiates the way he is engaged in practice and contributes to that practice (Smith, 2012). Adaptation to a new or changed occupational role can often instigate such activities.

Designable elements affording developing a vocational identity

Epistemic elements

The main practice that seems to elicit vocational identity learning is participating in the profession. Examples we found are:

- Participating in an action research community by occupational therapists that elicits learning about what it entails to become more scholarly (Ennals et al., 2016);
- Participation in Saturday clinics for an underserved population that elicits future health professionals' thinking about representing their profession and working in teams with professionals from other disciplines (Lie et al., 2016);
- Teaching internships that elicit thinking about how student teachers see themselves as (future) teachers (Schoeman and Mabunda, 2012).

Other, more pre-structured and supportive tasks or assignments related to participation in work are hardly mentioned. The work itself seems to afford learners thinking about the type of professional they want to become and the way they identify themselves with the profession in question. Participating in work also seems to elicit negotiations about (future) occupational roles and the accompanying norms and values of a profession.

Spatial elements

Following from the previous paragraph, the workplace can thus be considered the most important setting that initiates thinking and learning of (future) professional about their vocational identity. Workplace learning, for example via apprenticeships, can be a way for students to cross a boundary (Akkerman and Bakker, 2012), which elicits their thinking about the kind of professional they want to be (Schoeman and Mabunda, 2012).

Instrumental elements

Several tools, objects, and artifacts play a role and they are closely related to the vocational practice in question (e.g. a bakery setting including ingredients and machines or blog posts written by occupational therapists doing research; see e.g. Ennals et al., 2016; Chan, 2013). Typical for vocational identity development is that these instruments are actively used by the (future) professionals or sometimes even created by them. Creating an artifact, e.g. writing a blog post, can encourage learners to reflect about who they are and who they want to be (Howell, 2009).

Social elements

Development of a vocational identity is supported by participating in a community of other learners. Other learners are seen as fulfilling the role of representative of the profession, as (future) colleague, in such communities. In the communities, they share experiences and reflect collectively on what it means to work in a certain practice and on how to align with the norms and values of that practice (Ennals et al., 2016; Herrera et al., 2015; Howell, 2009). Besides peers, a broad range of significant others, such as educators in school or at the workplace, co-workers, and even the learner's family can support identity development. Educators frequently fulfill the role of role model or socializing agent (Ferm et al., 2018; Schoeman and Mabunda, 2012) and in that role they are being observed by learners or provide feedback. Clients or, in case of student teachers, pupils can also play a role as significant other. They may serve as a mirror for (future) professionals and make them realize how they have to adapt their occupational role to their needs (Smith, 2012).

Temporal elements

In the included studies, little direct information can be found regarding temporal elements that afford developing a vocational identity. What we do see, is that vocational identity development seems to occur at several points in time during relatively long learning trajectories (e.g. when switching to a new profession, when starting a new internship at a new workplace, when participating in series of site visits). This supports a common assumption that identity development is an ongoing process during a person's career (Beijaard et al., 2004). The transition to a new real-life work setting or to a new occupational role is an important starting point for renewed thinking about oneself as a professional (Smith, 2012).

Conclusion and discussion

In the included studies, a variety of designable elements which may afford learning *for* and *in* vocational practice can be found. The studies focused on learning processes and activities which could be related to three foci: learning how to act in vocational practice, developing vocational knowledge, and developing a vocational identity. In many studies, these foci were described in close relation

to each other, which can be explained from the socio-cultural view that was present in the included articles (Colley et al., 2003). From this view and in line with Leont'ev (1978), thinking and acting are often seen as inseparable and embedded in social practice. For example, a learning process like vocationalizing concepts will probably most directly contribute to developing vocational knowledge, but acting in vocational practice is needed in order to be able to vocationalize concepts and the process of vocationalizing concepts might, in turn, improve learners' ability to act as a professional.

Looking at the designable elements of learning environments, some overlap between which elements might enhance which learning can be found as well. Regarding *epistemic elements*, learning while working on occupational tasks, for example during apprenticeships, has a very prominent role. Other, more classical tasks or assignments are sometimes found to support developing vocational knowledge, but such tasks play a much smaller role in learning how to act in vocational practice and almost no role in developing a vocational identity.

Regarding *spatial elements*, a combination of locations/spaces at school, at work, and sometimes integration of those two via incorporation seem to be typical for eliciting learning for and in vocational practice. Of course, this is not a new insight, but our review shows which learning processes and activities are supported by which of those settings. Regarding learning how to act in vocational practice and developing a vocational identity, learning can be linked most clearly to work-based settings. With respect to developing vocational knowledge, we still see a more prominent role for school-based learning. At the same time, simulated work settings (e.g. school-based restaurant or mini-enterprise) also afford developing vocational knowledge.

Instrumental elements, like tools, objects, and artifacts play an important role in learning for and in vocational practice. They enable (future) professionals to do the work at the workplace or in simulation work settings in school and, as such, support learners in their learning how to act in vocational practice and their vocational knowledge development. Tools, objects, and artifacts are actively used and sometimes also created by learners. In relation to development of a vocational identity, they may serve as boundary objects or markers of a profession and of the norms, values, habits, and procedures related to it.

The importance of *social elements* in a learning environment becomes clear from the results of our analyses. Interaction between (future) professionals and significant others fulfilling different roles is key for learning for and in vocational practice: without interaction, the other designable elements will lose most of their strengths. A broad range of possible significant others becomes visible, including peers, educators in school or at the workplace, co-workers, clients, and family. The learners and significant others fulfill a variety of roles. Interaction between learners or peers in the role of colleague-in-training is visible in many studies. They support each other's learning by observing one another, discussing experiences, asking questions, providing or receiving feedback, thus functioning as a community of learners. Educators play an important role in the interaction regarding development of vocational knowledge. In the role of senior colleague or expert, they support learners in articulating concepts, vocationalizing concepts, or conceptualizing and concretizing concepts. Teachers are also role models in encouraging students to take initiative and responsibility, and as such their learning how to act as professionals.

The *temporal elements* which may afford learning for and in vocational practice can be discussed at two levels: at the level of distinct learning processes and activities or at the level of an overall learning trajectory. At the level of distinct processes and activities, we can conclude that the studied articles do not provide much insights. While studies on learning environments in vocational education sometimes mention intentionally designing opportunities to pause or interrupt ongoing work for instructional purposes (Bouw et al., 2021a), the reviewed literature on learning for vocational practice did not include evidence on what such measures may afford in terms of learning processes and activities. At the level of overall learning trajectories, we can conclude that timeframes and planning can be either more strict or more fluid. Strict temporal elements include distinct timeboxes for learning at school or learning at work. More fluid temporal elements include alternating learning in different settings, interspersing learning at school with shorter or longer periods of learning at work. Time becomes even more fluid when learning at school and at work occur more or less simultaneous. In some studies we saw the benefits of more fluid, simultaneous planning, for example when work experiences are immediately discussed, thus affording extension of a vocational repertoire, developing vocational knowledge, and contributing to the development of a vocational identity.

In sum, the main differences between the three foci that we found can be described as follows. In the included literature, learning how to act in vocational practice seems to be frequently supported in or by means of work-based settings or in-school work settings similar to vocational practice. Instrumental elements and social elements (co-workers as significant others) play a crucial role in this respect. Development of vocational knowledge, conversely, seems to be supported in school-based settings, possibly because of the presence of an explicit teaching role (social elements) and opportunities to pause in order to discuss the use of concepts (temporal elements). The third focus, i.e. the development of a vocational identity, seems to be enhanced in learning environments related to or resembling every day work, which might elicit (future) professionals' thinking about the kind of professional they are or want to be. Such environments often consist of a configuration of all designable elements, but are not always explicitly designed for the purpose of identity learning. Intervention meetings, focused on looking back at learning experiences in those every day work settings might strengthen vocational identity development (e.g. Akkerman and Bakker, 2012).

By focusing on designable elements that were described in studies about learning for and in vocational practice, we were able to provide insight into the elements of learning environments that can be influenced by educational designers or educators when they create these learning environments. When creating learning environments, a question that remains is whether and how affordances are perceived by learners and whether the learning processes and activities actually emerge as intended. It is known that learners, and also significant others, tend to interpret a learning environment and its affordances from their own frame of reference. Personal interpretation, combined with personal preferences they might have for certain types of learning and their current vocational repertoire, determine the actual learning processes and activities that unfold. For this chapter, we started our analyses from these actual

learning processes and activities and reasoned back to what might have afforded such learning. While the frames of reference and repertoires of the learners and significant others are of course still a factor, we think this approach provides relevant insights about how to design for learning.

Background

The recent advancement in information and communication technology (ICT) and the growing interdependence of the world's economies and cultures are constantly reshaping the education landscape. Recently, the World Economic Forum has released a report on the future of jobs in the fourth industrial revolution (4IR). 4IR builds on the third revolution (i.e., the digital revolution) and represents a fundamental change in our society and world economies. As an era of cyber-physical systems, the internet of things, and network, 4IR promotes a real-time world where information is instantly provided, and almost everything can be delivered directly to your door. It is the convergence of digital, physical, and biological innovations, such as artificial intelligence, robotics, augmented reality, 3D printing, and genome editing. This revolution has resulted in profound social, economic, political, and cultural transformations on a global scale. Some jobs will disappear, while others grow. Some skills will be displaced, while others thrive. [Table 1](#) shows the top ten trending and declining skills by 2022 ([World Economic Forum, 2018](#), p. 12).

However, 4IR has been heavily criticized for being technology-centric in which smart technologies, automation, and connectivity are overly emphasized. This developing scenario has eclipsed the service of humanity and instigates a lack of confidence of humans in new technologies that take humans out of the industry. As a response to this emerging concern, the fifth industrial revolution (5IR) came about, which is the synergy between human intelligence and technology to further increase efficiency ([Nahavandi, 2019](#)). It is a period of development where humanity is brought back to industry along with the advancement in technology. To put it simply, 5IR is the humanistic version of 4IR with the ultimate purpose of contributing to the quality of human life and not displacing humans.

These developments fundamentally compel the field of education to adapt (i.e., Education 5.0) and produce 21st century multiliterate learners who are capable of contributing to and engaging in this knowledge-based innovation-driven society. In response, educational agencies in many countries have revisited and beefed up their respective curricula to address societal and economic demands. However, these curriculum reforms should not only focus on producing employable and ICT literate students but also socially critical and productive citizens ([Jackson, 2014](#)). The same effort has transcended to the field of language education, in which several language curriculum reviews have been initiated. However, several studies (e.g., [Barrot, 2019a](#); [San Isidro, 2018](#); [Zhu and Shu, 2017](#)) have reported some challenges in developing and implementing state-of-the-art language curricula. Thus, this paper seeks to address some of those by offering insights into how a language curriculum innovation may be adopted and implemented. In other words, this paper offers a new curriculum design known as Language Curriculum 5.0 (LC5). LC5 is an innovative-producing curriculum that focuses on developing future-ready and competent communicators within the 5IR milieu. Specifically, the first section briefly explains the context of language curriculum innovation. The second section discusses the characteristics and components of the LC5, while the third section talks about key challenges in implementing this curriculum innovation. The paper concludes with suggestions on how can an evidence-based language curriculum innovation be systematically implemented. Since language curriculum is evolutionary rather than revolutionary, this paper does not advocate that time-tested practices be abandoned. Instead, it seeks to add value to what has already been existing. It is also worthy to note that this article is written within a mainly Philippine curriculum research tradition to highlight different perspectives and contexts.

Table 1 Trending and declining skills by 2022.

<i>Trending skills</i>	<i>Declining skills</i>
Analytical thinking and innovation	Manual dexterity, endurance, and precision memory
Active learning and learning strategies	Verbal, auditory, and spatial abilities
Creativity, originality, and initiative	Management of financial and material resources
Technology design and programming	Technology installation and maintenance
Critical thinking and analysis	Reading, writing, math, and active listening
Complex problem solving	Management of personnel
Leadership and social influence	Quality control and safety awareness
Emotional intelligence	Coordination and time management
Reasoning, problem solving, and ideation	Visual, auditory, and speech abilities
Systems analysis and evaluation	Technology use, monitoring, and control

English curriculum in the Philippines

As a response to students' poor performance in the National Achievement Test (NAT) and standardized English proficiency tests, the Philippine government introduced the Language Arts and Multiliteracies Curriculum (LAMC) in 2013. This curriculum reform sought to produce multiliterate and communicatively competent students to thrive in this innovation-driven society (Department of Education, 2016). Unlike its predecessor, LAMC is decongested by adding two more years of English courses (i.e., *Reading and Writing*, *Oral Communication*, and *English for Academic and Professional Purposes*) in the senior high school. LAMC also incorporated some pedagogical changes. First, it adopted the Mother-tongue-based Multilingual Education (MTBMLE), which uses the students' mother tongue as a medium of instruction from grades 1 to 3. Second, it shifted from NAT to end-of-grade 6, 10, and 12 assessments. Finally, it reduced the time allotment for English subjects both in elementary and junior high school levels. Despite these efforts, recent studies (e.g., Barrot, 2019a) have revealed that LAMC fell short in aligning it with 21st century learning context and established language learning and teaching principles. The findings also revealed that LAMC lacks specificity and coherence, which may contribute to widening the gap between the intended and implemented curriculum as well as what learners need to learn and what teachers want to teach. Thus, Barrot (2019a) highlighted the need to adopt an evidence-based and future-proof English curriculum.

Language curriculum 5.0

Forms of language curriculum

A language curriculum is a document usually prepared by a leading or government education agency that guides the teachers, teacher-trainers, textbook developers, language testers, and other key stakeholders (Celce-Murcia and Olshtain, 2000). It is an educational document that undergoes constant evolution as the field of language education expands. A language curriculum can be content-based, process-based, and product-based. A content-based curriculum focuses on at least three different contents, namely linguistic, thematic or situational, and subject-matter. A process-based curriculum, on the one hand, focuses on language learning and the teaching process. It may either be a needs-based, task-based, or learner-based curriculum. And then, there is the product-based curriculum that puts emphasis on the outcome of the course.

Given the current language educational landscape and advances in technology, language educators are urged to consider taking a paradigm shift in curriculum development. A state-of-the-art language curriculum should be able to see the future and be able to match the target skills of the curriculum to the demands of future jobs and society. As recently reported in the *World Economic Forum* (2018), 65% of children who entered schools today are likely to land in jobs that are not yet existing today. This scenario compels all curricula to be "ahead of its time" and shift toward Curriculum 5.0, which can be adapted in different subject areas. In the case of language education, it is LC5. Unlike the existing curriculum that is primarily product-based, this language curriculum innovation is a layered type of curriculum that systematically fuses the features of the different forms of curriculum (Barrot, 2015a; Brown, 1995). This means that while the curriculum targets the achievement of outcomes, it equally emphasizes the process of achieving such outcomes. Meanwhile, content is heavily fused into the curriculum as a means to achieving the outcomes and performing processes.

Balancing outcome and process

Equally important as the output is the process. LC5 highlights the significance of teaching processes in a language classroom. This requires curriculum developers to cover learning strategies as one of the focus areas in LC5, a feature underrepresented in the current English curriculum, particularly in the higher grade levels. Teachers can also be urged to demonstrate or model for the students the processes in creating spoken, written, or multimodal outputs (*Curriculum Planning and Development Division*, 2020) through the teacher's guide in LC5. The value of emphasizing the process is it makes learners realize that a language

is a tool for higher purposes and not an end in itself. The process orientation is associated with the task-based, experiential, and humanistic approaches in which the focus is on the learning process rather than the learning products alone and formative rather than summative assessment. An example of a language curriculum that integrates process orientation is the Singapore English Syllabus 2020.

Technology integration

The third important characteristic of a language curriculum in a 5IR environment is technology integration. ICT has significantly changed the landscape of language education across contexts. It even led to the emergence of a new subfield in language education known as technology-enhanced language learning (TELL) which refers to learning a language in any context with, through, and around technologies. Given this, it is inevitable that ICT be systematically integrated into language teaching and curriculum, not as a method, but as a powerful tool in enriching content and creating a diverse learning environment (Kenning, 2007; Wilkinson, 2016). Unlike the LAMC that is silent about ICT integration (Albuero et al., 2019; Barrot, 2019a), LC5 comprehensively and explicitly discusses how ICT can be used as a “tool” for teaching, learning, and assessment and how it can be used as a “tutor” for developing learners’ ICT skills. However, doing so may raise few issues, such as the lack of technical skills of teachers and students and insufficiency of ICT resources.

Closely related to ICT integration is the development of learners’ multiliteracies. Multiliteracy refers to learners’ ability to collect and/or retrieve information, organize and manage information, evaluate the relevance, quality, and usefulness of information, and generate accurate information through the use of available resources (Educational Testing Service, 2007). With the introduction of multiliteracy, a new form of pedagogical construct emerged, coined as multiliteracy pedagogy. It tasks LC5 to provide learners with opportunities to access, evaluate, search, sort, gather, and read data from various multimedia and multimodal sources. The multiliteracy skills that need to be developed among learners are basic literacy (numeracy and language proficiency), scientific literacy (knowledge of scientific concepts and processes), economic literacy (knowledge of economy), technological literacy (knowledge and skills in using technology), visual literacy (ability to process moving and non-moving images), information literacy (ability to process and evaluate information from various media), and multicultural literacy (ability to understand and relate with one’s culture and of others).

Sociocultural aspect of LC5

Aside from focusing on how language is learned and should be treated, a state-of-the-art language curriculum puts equal emphasis on how language functions as a medium for building interpersonal relations, social transactions, and intercultural competence. While there are attempts to fuse the sociocultural aspect of language learning into the LAMC, such integration is trivial as it stops at the realm of intention. Therefore, LC5’s goal is not just to help learners acquire language skills but also to help them perform social functions, actively participate in the community where they belong, and contribute to self- and social transformation. This idea is based on the principles of transformative learning and critical pedagogy that takes a functional-interactional view of language. Transformative learning goes beyond the skills, process, and content knowledge acquisition; it is a learning theory that allows learners to question how and what they know about life experiences such as culture, religion, politics, and personalities (Mezirow, 2000). In the same vein, critical pedagogy refers to a set of education principles that relate classroom experience to social transformation and wider social context to promote justice and equality (Akbari, 2008; Crookes, 2012). To translate these principles into tangible concepts, LC5 may need to specify themes, texts, and tasks that are not just prepared to impart knowledge but believed to be socially and culturally constructed to empower people. LC5 should also be able to help learners reflect on their own culture and life experience, critically view the society through dialog with others and transform society through active social actions. Community-based service learning or participatory learning communities may be explored for this purpose as it allows learners to have the power and control, through their active participation, to make their lives and world better (Schneider, 2019). Through these strategies, the curriculum links the classroom with students’ realities beyond their school.

Globalization and localization in language education are not two opposing views. Rather, they are complementary views that make language curriculum global without compromising local identity. Reconciling these two views has led to the new construct known as glocalization which is a mixture of global and local knowledge and practices. To simply put it, glocalization takes on the mantra, *think globally and act locally*. Having a glocalized language curriculum allows learners to understand the language and behavior of other cultures and communicate with people from other cultures without losing their local identity (Byram, 1997; St Clair and Phipps, 2008). There are two ways that glocalization can be adopted for LC5 development. First, LC5 should present English as an international commodity (also known as world Englishes) rather than a property of English-speaking countries. It has to recognize its own variety of English appropriate for its local context. Second, LC5 needs to consider intertextuality when selecting texts. This means that suggested texts in LC5 should be carefully selected in a way that there is a balance and link between local and foreign texts (i.e., spoken, written, or multimodal). Therefore, learners should be exposed to various texts of local and international concerns, allowing them to bring a local issue to a global context.

Culture and curriculum are two interdependent constructs (Byrnes, 2010; Lavrenteva and Orland-Barak, 2015). Any language curriculum cannot exist without considering the culture where it is situated. LC5 developers are expected to consider the setting (interactional and physical), behavioral environment (kinetic and nonverbal), language, and extracontextual factors (sociopolitical,

historical, and environmental). Although curricular borrowing (i.e., adopting the language curriculum of other countries) may look practical, it usually fails locally as it contains elements that do not fit with local culture and norms (Carless and Harfitt, 2013). Take for example the use of strong task-based language teaching in some Asian countries (Butler, 2011; Cao, 2018). LC5 has to be personalized as well by considering the personal interest, motivations, and learning style of the target learners prior to its development. In many cases, curriculum developers use their common-sense intuition based on experience and practical knowledge during the development process. Although it is practical and has some significance, decisions solely based on intuition may have some serious setbacks as it is prone to overestimation or underestimation (Barrot, 2019b). As such, curriculum developers are urged to survey learners to get hold of data needed for a more personalized language curriculum. Nonetheless, LC5 needs to be flexible as well to cater to the learning needs and styles of other learners (Nel et al., 2016). A flexible curriculum is designed to be accessible for diverse learners regardless of their background and creates many opportunities for learners to attain the ILOs. It also allows teachers to explore various possibilities in executing a lesson, thereby empowering them and developing their creativity as facilitators of learning. Adopting a flexible curriculum means prioritizing quality over quantity. Certain provisions in LC5 need to provide opportunities for schools and teachers to individualize and contextualize the curriculum to their respective learners.

Self-management and life skills

Another humanistic feature of LC5 is its emphasis on learners' development of their self-management and life skills. Regrettably, these skills seem to be neglected in many curricula, as in the case of the Philippine K-12 curriculum. This set of skills comprises, but is not limited to, adaptability, managing complexity, self-direction, self-monitoring, curiosity, resource utilization, decision making, risk-taking, emotional control, and sound reasoning. Young and adult learners alike are prone and vulnerable to high-risk situations and may eventually succumb to these challenges. But when equipped with essential life skills coupled with psychosocial support from their environment, learners can deal with these challenges effectively (The Partnership for 21st Century Learning, 2015). The question is how they can be incorporated into LC5. One approach is to embed these skills into the affective ILOs in the learning guide. In such a case, life and self-management skills may be selected based on the set of texts or themes assigned in each lesson, quarter, or unit of LC5. Additionally, these skills may be reinforced in the suggested activities and assessment sections of the curriculum.

One way to reinforce self-management and life skills is through problem-based language learning, where learners are asked to perform a task similar to real-world problems that they may encounter beyond the four corners of the classroom. It specifically taps learners' creative, innovative, and analytical skills while allowing them to experience complex problem-solving situations (Chen and Kuo, 2019; Moallem et al., 2019). To incorporate this into the curriculum, well-defined intended learning outcomes (ILOs) and contexts that target the development of learners' problem-solving skills may be explored.

Outcomes-based pedagogy

In the case of some curriculum reforms (e.g., LAMC), although the target learning competencies or outcomes are comprehensive, problems on constructive alignment and specificity have been observed. In addition, these learning competencies or outcomes tend to be overly cognitive and academic, making it difficult for learners to bring their learning beyond the four walls of the classroom. On this note, LC5 systematically incorporates the principles of outcomes-based pedagogy to produce work-ready graduates who possess skills and abilities that match the demands of industry and community. Central to outcomes-based pedagogy are the ILOs and the ways on how the curriculum and teaching-learning processes revolve around achieving these ILOs (Biggs, 1996; Spady, 1994).

To achieve this, Biggs (1996) proposed the idea of constructive alignment, which emphasizes the consonance among the teaching-learning activities, assessment methods, and ILOs. To apply this in LC5 development, four steps must be taken: (1) clearly define the ILOs; (2) specify the teaching-learning activities that will scaffold the achievement of the ILOs; (3) assess students' performances and check how they match the ILOs; and (4) rate the performance. Note that multicomponential assessment plays a key role in an outcomes-based curriculum; thus, it should be clearly specified in LC5. By multicomponential, we mean using various forms of assessment (formative and summative, traditional and alternative, self-, peer and teacher assessment, formal and informal, assessment of learning, assessment for learning and assessment as learning) to get the full picture of learners' progress. During assessment activities, emphasis should be given to the process, formative assessment, and authenticity to mimic real-world contexts. However, all assessment activities should be within the social realities of the learners. For instance, a grade 3 pupil should not be given a bank transaction task. Although it is authentic, the task is beyond the social reality of a grade 3 pupil.

LC5 components

Given the features above, Table 2 presents the suggested components of LC5. The list is not exhaustive, but it will provide a good idea of how LC5 looks like.

Table 2 LC5 components.

<i>Components</i>	<i>Description</i>
Context of language use	This section explains how language is viewed and used in a given context and the local and global factors that shape it. It concludes with the desired outcomes for language learners of the curriculum.
Language curriculum framework	This section presents the schematic framework and key features of LC5. It also explains the general and specific aims of the language curriculum and how its different elements contribute to achieving them. These elements include the theories of language and language learning (e.g., sociocognitive theory), the language teaching and learning principles (e.g., social interaction and collaboration, macroskills integration, microskills integration, form-meaning connection, contextualization, intercultural competence, ICT integration, spiral progression, process orientation, differentiation, reflective learning, and 21st century learning) and the learning processes (e.g., problem-based, project-based, and task-based learning) that underpin the curriculum (Barrot, 2014, 2015b).
Areas of language learning	This section maps out the various language learning ILOs at multiple levels and shows their constructive alignment. The different ILO levels include core learning area ILOs (i.e., overarching ILO across all grade levels) per macroskill or cluster of macroskills; key stage ILOs (i.e., overarching ILO for primary and for secondary levels), grade-level ILOs (i.e., ILOs specific to one grade level); and focus area ILOs (i.e., a set of grade-level ILOs in each focus area, such as listening, reading, speaking, writing, representing, viewing, grammar, and vocabulary). It is expected that content, skills, strategies, and attitude/values are sufficiently addressed in the crafting of ILOs at multiple levels.
Language assessment guide	Since multicomponential assessment plays a key role in LC5, a comprehensive language assessment guide merits serious consideration. This section details the language assessment framework and activities that align with the goals of LC5 and its different ILOs. It also provides specific guidelines on how assessment can be implemented in different language learning contexts.
Language teaching guide	This section details the role of teachers in language classrooms and offers some approaches, methods, techniques, and strategies in implementing the lesson. It also offers tips on ICT integration and additional resources for language teaching. Finally, this section provides sample lessons that reflect LC5 principles and ILOs.

Implementing an evidence-based language curriculum 5.0

To better understand and implement curriculum reforms, it requires to be viewed from multiple perspectives. Unfortunately, teachers and other key stakeholders have very limited involvement in the work of the panel and the development process in many countries, such as the Philippines. As a way to move forward, the government education agencies may take a more transactional approach that allows end-users (i.e., teachers, school leaders, and students) and other key stakeholders to be actively involved in the development process from designing the curriculum to its implementation. One way to do this is to intensify public hearings and meetings that invite end-users to make comments on the drafts before the curriculum is finalized.

To do this, the following steps are recommended. As shown in Fig. 1, the first step is to create a technical panel that will bring together language curriculum experts (i.e., practitioners and researchers), teachers, students, school leaders, government education agencies, professional organizations, industry, community leaders, and parents. This multisectoral panel is tasked to provide multiple perspectives in curriculum development and implementation. Second, it is crucial to survey the students on their learning preferences, learning style, interest, and motivations. The collected information can be used in selecting tasks, texts, and topics, crafting learning competencies, and choosing appropriate resources, among others. Third, the crafting of the preliminary curriculum may be initiated once all necessary information is collected and analyzed. A team of expert curriculum developers may take the lead during the drafting stage. Fourth, the LC5 draft may be subjected to experts' face and content validation to further refine it prior to piloting. During content validation, experts evaluate the alignment, specificity, and coherence of the LC5. Face validation, on the one hand, focuses on the clarity, accuracy, and aesthetics of the curriculum. After the experts' validation phase, the draft curriculum may be piloted in strategic areas that represent various demographics of learners for at least one year. Consider the diversity of the selected areas during piloting so that the curriculum would be able to capture as many learning contexts as possible. Diversity relates to location (urban, suburban, and rural areas), performance (high performing and low performing schools based on achievement tests), resources (rich and low resources), socioeconomic status (class A, B, C, D, or E), and language proficiency level (high, mid, and low proficient) among others.

The Evaluation and Monitoring Team (EMT) plays a crucial role in the success of the curriculum implementation. It will take the lead in assessing the impact of LC5 on teachers, school leaders, and learners. The EMT may conduct classroom observation that focuses on the implementation challenges and impact of resources on instructional delivery and learning. The team may also interview teachers and school leaders to assess their level of understanding of LC5 and to seek suggestions from them in addressing the encountered challenges. For learners, the EMT may take the lead in assessing their performance before and after the implementation to see the viability of the curriculum in terms of learning. Learners may also be engaged in a focus group discussion, allowing them to voice out their learning experience. In the first place, they are the ultimate consumers of curriculum innovation. All the information collected during the monitoring and evaluation phase may be used to further refine the curriculum and its implementation strategies. Another round of piloting is preferred but not necessary. Once the curriculum and the implementing guidelines are finalized, the curriculum developers and the technical panel may begin developing the teaching guide, sample lesson plans, and

Fig. 1 Schematic representation of implementation framework.

assessment guide to ensure that sufficient information is given to the end-users (i.e., teacher, school leaders, and textbook developers). The assessment guide should be comprehensive enough to cover all the ILOs in LC5. When all things are set, full implementation of the new curriculum may commence. Since monitoring and evaluation is as crucial as the implementation, the central governing body or the technical panel may institutionalize an evaluation and monitoring department to ensure the effective implementation of LC5.

Implementation challenges

Once LC5 is developed, one may think that the job is done, but it is not. Development is just one part of the pie; curriculum implementation is another matter. Curriculum implementation is a complex process, which needs thorough planning and coordination with various stakeholders. However, in some cases, it is not given the level of attention it deserves. And so many problems arise, but I will only focus on few major ones based on [Vidovich's \(2002\)](#) policy cycle framework that discusses three contexts: the contexts of influences, context of practice, and context of policy text production. The context of influence refers to the struggles among stakeholders over the construction of policy discourses. The context of policy text production refers to the articulation of the curriculum despite its inconsistencies. Finally, the context of practice relates to how various stakeholders (e.g., teachers and school leaders) interpret the curriculum.

The first major challenge confronted when implementing curriculum innovation is the gap between curriculum intentions and how they are translated and learned at the classroom level. One factor that contributes to this widening gap is the centralized and bureaucratic process in its development and implementation. Common to the language development and implementation process is the top-down approach in which policies and procedures emanate from a central governing body. The problem with this approach is that teachers lack ownership and participation in the reform. And if ever they attempt to implement it, such an effort

is superficially adopted. Aggravating the situation is the potential clash between what the curriculum says and what the teacher believes and practices. In such a case, it is unlikely that teachers take curriculum innovation seriously (Carless, 2013).

The second major implementation challenge arises from the curriculum itself. Developing a pedagogically sound, specific, and coherent curriculum is not an easy task because it requires the government to bring together the right people for the job. So if the development process fails to properly execute coordination or fails to choose the right people, such failures may lead to inconsistencies and content issues. The common problems seen in a not so well-thought off language curriculum are its lack of alignment, specificity, and coherence (Barrot, 2019a; Howard and Millar, 2008). It has been observed that some language curricula fell short in integrating the established principles of language pedagogy and lack solid pedagogical frameworks that would underpin the curriculum. Consequently, the language curriculum becomes a hodgepodge of many elements without focus. Details in the elements and procedure of any language curriculum are important to its successful implementation. However, not all sufficiently explain their intentions, principles, and features. Take for example a language curriculum that lacks details on ICT integration as a tool and as a tutor, lacks domains of language skills (e.g., viewing and representing), and lacks an assessment guide. In terms of coherence, some learning outcomes and topics are introduced without sufficient scaffolding. Meaning, there is no systematic progression of learning outcomes and standards. Within one lesson, constructive alignment is sometimes breached. For instance, a week's lesson requires learners to produce a narrative, but the target linguistic form under the grammar domain is *prepositions* instead of *past tense*. In some instances, the target grammatical item is *prepositions for giving directions*, but the target text under the writing domain is a *feature article*.

The last implementation challenge is how the teachers and other stakeholders interpret the curriculum. As earlier mentioned, lack of substantial participation from teachers and school leaders and the curriculum incoherence, vagueness, and misalignment contribute to its misinterpretation and misapplication in the classroom. The other factors that contribute to the misapplication of the curriculum are uncommitted school leadership, lax monitoring and evaluation, minimal involvement of parents, limited school resources, poor school environment, teachers' administrative load, illiteracy levels of learners, limited training, mismatch between national standardized assessment thrust of the curriculum, and insufficient time (may be linked to overcrowded curriculum) that forces teachers to prioritize quantity over quality.

Conclusion

This article has shown the recent social and economic developments and how they impacted education, particularly language education. As a way to address the demands of the 5IR environment, LC5 is proposed. This state-of-art curriculum aims to develop future-ready and competent communicators who can thrive in an innovative-driven environment. The key features that set LC5 apart from the conventional are as follows: problem-based, process-oriented, technology-based, multiliteracy focused, socially and community-oriented, life skills and self-management oriented, outcomes-based, glocalized, and contextualized and personalized yet flexible. Nonetheless, possible challenges for its implementation were presented, and strategies to address them were offered.

While this paper offers insights into designing and implementing a state-of-the-art language curriculum, will and commitment of key people remain to be the key ingredient. No amount of curriculum innovation will succeed without the concerted effort of its key stakeholders, namely the policymakers, the school leaders, the teachers, and the students. As a final note, the proposed language curriculum innovation is suggestive rather than prescriptive. It is merely the beginning of the new era of language curricula. And as long as the society evolves, so as the curriculum.

Introduction

In all its visible and invisible forms, school architecture has undergone an extensive transformation. In the middle of the 19th century, the most common type of school in Denmark was the village school, later known as “the thatched school” because of the frequently used roofing material. Such schools would typically be comprised of a small building with a schoolroom at one end and the teacher’s residence at the other. Inside the schoolroom, the children sat at long tables with fixed benches, looking up at the teacher’s desk. A blackboard that could be written on with chalk hung on the wall or stood on the floor next to the teacher’s desk. It was also common for city schools to house both the schoolroom and the teacher’s residence. If there were a lot of children, there might be two separate teaching spaces (Gjerløff et al., 2014). Schools in Denmark today are not only much bigger in size, but also have a wide range of designs and may be built using bricks, steel or glass, with white, bright green or wooden facades. Some stick to traditional classrooms dotted along long corridors. Others contain so-called innovative learning spaces, with rooms in various sizes and shapes. The interior might comprise a simple arrangement of chairs and tables in more or less orderly rows, but teaching spaces often include clustered arrangements, sofas and broad stairs meant for sitting as part of the core furnishings.

The history of schooling is continuously layered within the compound landscape of school buildings with different historical origins, often lying side by side or built into each other as expansions or modernizations of the original schoolhouses. At the same time, school architecture and the physical landscape of schooling exhibit explicit attempts at change when new material designs are invented and hold inertia in the sense of often long-lasting buildings (see Figs. 1 and 2). Buildings from the same time, but with highly dissimilar architectural forms may even be shaping the same local scenery, revealing the coexistence of different educational convictions, as in Mark Dudek’s example of how the conflict between traditional and radical approaches to education was reflected in the compound school architecture at the beginning of the 20th century (Dudek, 2002).

School architecture is about school buildings. It is walls, doors, windows and roofs. It is the building materials, colors, shapes and dimensions of teaching areas and classrooms. School architecture may also be understood as concerning the use and organization of space and about bodies, affects and cultural and sensory perceptions. Moreover, it may be seen as unavoidable that approaches to education, processes of learning and matters of more formal curricula inscribe or entangle themselves into this multi-dimensional and processual understanding of school architecture. This chapter aims to examine both the immediately decipherable and the more subtle links between school architecture and curriculum by viewing school architecture as not only a matter of the architect’s pen, but also as created through policies and pedagogies, as well as through teachers’ and students’ everyday use of space (e.g., Mulcahy and Morrison, 2017; Juelskjær and Rosén Rasmussen, 2019; Grosvenor and Rasmussen, 2018a; Boys, 2011). The paper primarily applies a European perspective, with particular focus on Danish and other Scandinavian examples. Even though the text seeks to explore a diverse range of empirical examples situated differently in space and time, the empirical outset will inevitably shape the analysis and its conclusions, not least when it comes to the question of the presence or absence of an explicitly formulated curriculum.

Materializing curriculum and educational discourses

The relationship between school architecture, the layout of school space and curriculum has a long history. In this history, school architecture and school interior designs of schools have sometimes been built with a direct reference to curriculum, but have more often been circuitously connected through practices and ideas of pedagogy and education. The variations in the presence and role of an explicitly formulated curriculum have been manifold and shifting across countries and through time (Tröhler, 2016). Therefore, exploration of the relationship between school architecture and curriculum entails ongoing discussion of the national and local sense-making regarding a curriculum—or sometimes its absence—vis-à-vis educational ideas and strategies. Nevertheless, the focus on the relationship between school architecture and the particular purpose of schooling at a given time and in a given place has been

a recurrent theme for educationalists, architects and politicians. In 1849, the American educationalist Henry Barnard wrote in his famous work *“School Architecture. Or, Contributions to the Improvement of School-Houses in the United States”*:

The style of the exterior should exhibit good, architectural proportion, and be calculated to inspire children and the community generally with respect for the object to which it is devoted. (...) Every school-house should be a temple, consecrated in prayer to the physical, intellectual, and moral culture of every child in the community, and be associated in every heart with the earliest and strongest impressions of truth, justice, patriotism, and religion.
Barnard (1848: 40).

Barnard writes about the school building in terms embedded in the discourses of his contemporaries, spun into a religious set of norms and significant to the development of schooling in the late 19th century. When evaluating if specific schools were “conducted as to promote habits of neatness and order, and cultivate good manners and refined feelings” (Barnard, 1848), Barnard reflected complementary discourses of hygiene and discipline that were significant in the development of not only schooling but also of school architecture in the late 19th century in the US but also in Europe (Dudek, 2002). Meanwhile, Barnard creates an explicit link between the purpose and the designed materiality of schooling (Willis, 2017). Likewise when expressing his concern for the state of his contemporaneous schoolhouses—their lack of ventilation, privies and, more generally, suitable facilities for schooling—he directly accentuates the importance of a proper schoolhouse for “the bodies, the minds and the hearts of the young and rising generations” (Barnard, 1848: 37).

The research literature on educational architecture has studied how shifting architectural, political and pedagogical ideas have helped shape the design of school buildings (Burke and Grosvenor, 2008; Darian-Smith and Willis, 2017). Analyzing school architecture based on its material surface, radical alterations in the architectural styles of school buildings stand out and may be patterned according to time and geographical space (Willis, 2017). As such, school architecture may be read as a materialization of educational—and architectural—discourses of schooling and thus of different historically situated ideas of schooling, its purpose and form (see Fig. 3).

Classroom curricula: forms and variations

School architecture may be read as a materialization of the understanding of—and disputes over—questions of curriculum, often in a broader sense of knowledge and pedagogy concerning what is considered important for the child and future citizen to learn and, not least, how this is best accomplished. One of the key elements in school architecture over the years has been the classroom. Looking at the classroom, its variations and transformations, its appraisals and critiques, enables an exploration of the interweaving of curriculum and school architecture.

John and Evelyn Dewey’s critique of contemporary schooling of the Western world in the early 20th century includes a description of the classroom—or schoolroom as they call it—depicting “rows of children sitting still at desks and listening to the teacher, speaking only when they are spoken to” (Dewey and Dewey, 1915). Thus, it is a school characterized by a certain disciplinary

Fig. 3 In 2016 the renovation of Engstrandskolen in the Danish city of Hvidovre included the mounting of gymnastics rings and climbing walls in the school corridor. This was in line with the latest (2014) school reform’s decisions on schools having to integrate at least 45 min of exercise into the ordinary school day for all students. instructional mode that is evinced by the physical ordering of tables and children. The description of the classroom also echoes how Danish classrooms at that time reflected and reinforced the dominant educational ideas. With the increasing number of children living in cities in the latter part of the 19th century, more schools were gradually being built. These schools were often public schools; they were larger, with several classrooms and the need for more teachers, who no longer lived on school premises (Gjerløff et al., 2014). For the most part, the schools were spread across several floors, with square classrooms symmetrically located around landings or long corridors. With the focus at the time on the importance of hygiene, sunlight and fresh air, classrooms contained large windows and the students' two-person desks were often available in three sizes to match the child's height (see Fig. 4). The ideal was that the child sat with a straight back with elbows in to the body. The light should preferably come in from the left as students were expected to write with their right hand. The teacher had an elevated desk facing the students (Coninck-Smith, 2011). Thus, teachers, with their gaze, were able to maintain order and induce students' self-discipline. Both were essential to the organized class teaching promoted by the Danish educator Ernst Kaper that gained ground in Danish schools in the early 20th century (Kaper, 1903).

The above image (Fig. 4) represents what is perhaps considered the archetypal classroom: symmetrically opposed square spaces; students seated in pairs at rows of tables, backs straight and facing the teacher's elevated desk. Nevertheless, as we shall see in the following, the form and function of the classroom gradually transformed during the 20th century through its entanglement with shifts in educational policy and the emergence of new educational rationales. Ernst Kaper's philosophy was itself a critique of the earlier interrogative classroom praxis, where the teacher selected and then questioned individual students (Knudsen, 2015). Kaper recommended that the teacher asked the whole class a question and then paused. The students able to answer should be allowed to raise their hand, after which the teacher could select a student to answer the question (Kaper, 1903). Thus, encouraging all students to be involved at all times through organized class teaching, Kaper's ideas could be seen as representing a subtle transformation of earlier uses of the classroom.

The rearrangements of the classroom were tied to the rethinking of teaching strategies and changing view of the child. In 1957, the Danish Ministry of Education's Building Research Committee published a report in collaboration with the National Building Research Institute. The aim of this report was "to explore how the classroom could best be utilized, and how a change in the room's organization and layout could support the new forms of teaching that had emerged with emphasis on both group teaching and individual teaching" (Undervisningsministeriet, 1957). The report gave examples of how grouped table arrangements, rather than tables arranged in rows, were conducive to more individualized and differentiated teaching. The tables could also be set up in a circle or horseshoe shape. In general, it was encouraged to change the physical arrangement of the classroom to suit the teaching about to take place. Of course, this required non-fixed tables and chairs instead of the old-fashioned desks, where the bench and table were attached. Furthermore, the new ways of using the classroom meant that larger rooms were preferable. While the classroom proposed in the report was still a room with four walls, the message was that teaching should look beyond these walls, using corridors and other spaces during lessons. The proposals in the report resonated strongly with the pedagogical experiments that had taken place within the framework of progressive pedagogy as early as the 1920s. In the Danish "Vanløse experiments" carried out 1924–28, there had been a focus on the individual child's developmental opportunities and creativity, the fixed sloping desks had been replaced by tables and chairs and students were allowed to move around freely in the classroom (Christensen, 2008; Gjerløff

et al., 2014). With the Ministry's report, these ideas were tied to the material arrangement of the classroom and written into the broader and more general guidelines and regulations for the school.

Open-plan schools were a more radical break with the classroom model in both architectural and educational terms. The first open-plan schools were developed in the US and in Great Britain in the 1950s and 1960s, before spreading to a number of countries in the following decades (Bennett and Hyland, 1979). Open-plan schools were built with large open spaces and have been described as "the crystallization of progressive ideals in both architecture and education" in the sense of being concerned with the child's individuality and curiosity and striving for social progress by extending teaching beyond traditional knowledge disciplines (Logan, 2017). With flexibility as the key principle in the organization of space, these schools had fewer walls and doors, movable wall dividers, mobile blackboards and easy-to-move furniture. The furnishings were usually less institutional and homogeneous and spaces were decorated with exhibitions of work produced by the students and in the classroom (Burke, 2019; Darian-Smith and Willis, 2017). Thus, the architecture of open-plan schools reflected a shift in the material conceptualization of schools, further evolving a so-called open-plan pedagogy took form in its multiple variations (Franklin, 2012). In general, open-plan school buildings did not come with a ready-made curriculum, but with an openness to new ideas and a call for teachers to experiment with curriculum design. For countries like Great Britain, where there was no national curriculum at the time, and Denmark, where bottom-up processes and teachers' freedom to choose teaching methods were highly valued, schools and teachers had genuine autonomy and space for curricular creativity (Krogh-Jespersen and Nørgaard, 2011). Nevertheless, despite significant variations in the layout and curriculum of open-plan schools, they were generally accompanied by calls for more democratic and socially transformative schooling and by ambitions of establishing less hierarchical relations between teachers and students, more participatory learning and a student-led curriculum (McLeod and Rosén Rasmussen, 2021; Silberman, 1973).

Despite the challenge represented by new approaches such as open-plan schools, the classroom remained a key element in Danish schools, and globally, throughout the 20th century. However, there was a re-emergence of a radical critique of the conventional classroom in the new millennium, where it was argued that there was a need for innovative learning spaces (Dumont and Istance, 2010; Benade, 2017). In opposition to the standard classroom, innovative learning environments have been characterized as multimodal, technology infused and flexible learning spaces, engendering pedagogies for students to become self-directed learners capable of navigating the complexities of a technology-mediated and knowledge based society (Byers et al., 2018). Whereas local curriculum development was embedded in the pedagogy of the open-plan school, it has been argued that innovative learning environments can help reimagine the school and support students' development of the skills and competences anticipated as necessary for 21st century societies (Cardellino and Woolner, 2020; Dumont and Istance, 2010; Sigurðardóttir and Hjartarson, 2011; Carvalho and Yeoman, 2018).

Critical examination of the classroom as a key feature of school architecture and a core element in teaching practices shows variations in how it has been conceived. Moreover, it exemplifies the shifting but ever-present relation between, on one hand, physical buildings and layout, and on the other hand, pedagogical ideas and practices—a relation within which architecture and curriculum are mutually entangled.

The relationship between school architecture and educational practice

The topic of school architecture and curriculum brings up another central question already raised in the text above and further developed in the examples from Barnard's writing, the shifting design and conceptualization of the classroom and the open-plan movement: What is the relationship between school architecture and educational practice? The relationship between the school's material properties, its educational purpose and educational practice has been a matter of ongoing discussion among educational practitioners and in the field of educational research. Empirical understandings of the entanglements of spaces in new school buildings and teachers and students' occupation of these spaces have ranged from viewing architecture as an expression of the (intended) practice of schooling to seeing it as supporting, shaping or even determining pedagogy and possible teaching strategies.

There has long been a belief in the impact of the physical design of school space on educational practice (see Fig. 5) in empirical approaches to school architecture and school space among politicians, educational thinkers, architects and other practitioners (Cooper, 1981; Wood, 2020). In a historical perspective, this belief was already present between the lines in Barnard's writings on the ability of physical surroundings to *promote* certain habits, manners and feelings. In the open-plan schools, the physical environment was to a large extent addressed as supporting the chosen educational activities and strategies (Rosén Rasmussen, 2021). In the sense of balancing between providing structure and encouraging exploration, the school environment has been designated "the third teacher" (Strong-Wilson and Ellis, 2007; Burke and Grosvenor, 2008). This understanding of space as an active agent, rooted in the philosophy of the Italian educational project Reggio Emilia, can be found in contemporary understandings of educational architecture (Pezzetti, 2020).

Belief in the transformative force of school buildings has been crucial in political approaches to the matter. Both UNESCO and OECD, as large international institutions, have had programs for developing the quality of school buildings worldwide that also strived for educational change and improvement (Grosvenor and Rasmussen, 2018b; Charteris et al., 2017; Townshend, 1998). The aim of the British school-building program Building Schools for the Future, which ran from 2005 to 2020, was framed in terms of educational and social change. While based on national guidelines, schools were asked to tailor their curriculum to the needs of their local community and the school's particular educational aims, before the material spaces of the new school buildings were designed (Krafft, 2012). Around the same time but on a smaller scale, the Danish municipality of Gentofte ran a project to renovate school buildings that had a similar goal of facilitating a transformation of the form and content of education (Leiringer and Cardellino, 2011). Some have argued that a utopian ideal of a bottom-up transformation of schooling and the curriculum lay at the

Fig. 5 A rendering showing how architects have interpreted, translated, and developed political and educational visions for a new school in Sundby, Denmark, to be built in 2022. The school is by the architects named a landscape school and is said to have a potential of drawing history and nature inside as well as encouraging spontaneous and integrated movement. Source: Henning Larsen Architects.

core of the design and practice of open-plan schools in the 1960s and 1970s (McLeod and Rosén Rasmussen, 2021). Meanwhile, the innovative learning spaces of the present day are designed as a contrast to the traditional classroom-based school (see Fig. 5) and are expected to support or even enhance strategies suitable for teaching the curriculum of the future (Deed and Lesko, 2015; Carvalho and Yeoman, 2018).

The academic analysis of school architecture and its relationship to curriculum and broader educational matters has been molded by the thinking of Michel Foucault and his notions of panopticon and governmentality (Piro, 2008; Simmons, 2010; Peim, 2005; James, 1991). Along these lines, the role of governance in educational architecture has been highlighted and school architecture has been interpreted as imprints of policies and pedagogies believed to have the potential to govern and shape the school and its inhabitants (Burke, 2005; Grosvenor and Rasmussen, 2018b; Wood, 2020). The conceptualization of architecture as means of governance grasps the perception of school buildings as supportive of curricular aims. It also pinpoints the belief in the buildings' ability to promote educational ideas and strategies recognizable in Barnard's writings and extrapolated in later visions of the physical environment as a key to broader transformations of schooling, the curriculum and the school system as a whole.

Within academia, there has been a move toward an understanding of space as social and relational, acting as a critique of the idea of space as a container (Massey, 2005). This echoes and reintroduces Lefebvre's focus on the social production of space. In these studies, the power of school architecture is further complicated as users or inhabitants of school buildings, and in a broader sense educational practices, are not merely seen as governed by the physical architecture of these buildings, but also as affecting and shaping it in both material and immaterial ways. Such understandings of space as social and processual further complicate the relationship between architecture and curriculum.

A socio-material approach developed with an outset in cultural geography and actor-network theory has reintroduced and reinforced a focus on the material aspects of learning environments by stressing the agency of the material, but still maintaining a social and relational understanding of space and even introducing it to analyses of the affective dimension of learning environments (Mulcahy, 2015; Mulcahy et al., 2015; Mulcahy and Morrison, 2017; McGregor, 2003, 2004). In these studies, there is particular focus on educational change and how this may be induced by a new learning environment. Nevertheless, the socio-material approach leads to an understanding of space, pedagogy and change as mutually constitutive. Recent influence from new materialist theories has shifted theoretical understandings of school architecture even further from the idea of space as a container and thus of school buildings as an external support for or promoter of an easily decipherable curriculum. In the new materialist approach to school architecture, school designs, pedagogical ideas and practices—and one might add curriculum in a narrow sense—are intrinsically linked and explained as coming into being and obtaining their specific meanings *through* each other. The focus is on process and entanglements, weaving both material and immaterial meaning-making of school architecture and design, teaching practices, pedagogical understandings and curricular provisions closely together over time, across space and in situ. Studies applying this approach are occupied with the detailed processes of becoming, for instance exploring the protracted construction and continuous adjustment of a school building and of everyday teaching practices. At the same time, these studies all pay attention to how this process of becoming is tied up in, draws on and feeds into broader local, national and transnational discursive processes, which include but also go far beyond political decision-making (Juelskjær, 2014; Coninck-Smith, 2017; Thyssen, 2018; Carvalho and Yeoman, 2018).

The theoretical conceptualization of space and materiality as something that is shaped by, shapes or is entangled in educational discourses and practices grasps to varying degrees the empirical and practical understandings of and approaches to school buildings

and school spaces among architects, school leaders and teachers. Moreover, the development of theoretical understandings of the physical (school) space and its implications for comprehending the relationship between school architecture and curricula has influenced the design of and the political and practical approach to school architecture and school space in general. Thus, acknowledging how theoretical and empirical understandings of space interweave is important coming to terms with changes in school design and, not least, the expectations to and the conduct of school architecture and school space.

Material transfers of curricular designs

The history of the relationship between material school design and curriculum has a strong international and transnational dimension. Because of the physicality of its matter, it is easy to trace and identify how architecture and material designs travel across national borders. Studies of school architecture in an international or transnational perspective most often single out how pedagogical ideas and architectural models travel together (Coninck-Smith, 2010a; Thyssen, 2018; Lundahl, 2016). Regardless of the subsequent processes of translation and implementation, the spread of material school designs often seems to have functioned as a spearhead for the introduction of new educational ideas and practices (see Figs. 6 and 7).

The entangled travel of school architecture and curriculum has assumed various forms over time. World's fairs have been put forward as an example of an international meeting point for the materiality and curriculum of schooling where particular school designs and new teaching methods have been promoted as coherent models. In the 1860s and 1870s, various educational artifacts, such as scientific instruments, charts, desks and tables, were displayed at the world's fairs. In 1871, the Swedish state funded the exhibition of a full-scale and fully equipped schoolhouse at the World's Fair in London. This was a prototype for the ideal schoolhouse of the future rather than an example of an actual Swedish schoolhouse, but nevertheless, it was an expression of the Swedish education system, including the use of object teaching and more specific national pedagogical ideas such as Sloyd (Lundahl, 2016; Lundahl and Lawn, 2015). The exhibition of the Montessori demonstration classroom at the Panama-Pacific International Exposition in San Francisco, California in 1915 provides a similar example. This time, the classroom was populated by children and visitors could watch classroom activities through glass walls. Based on Maria Montessori's ideas, the classroom was equipped with child-sized furniture and the focus was on what has been called a pedagogy of attention. The Montessori demonstration classroom has been described as important in spreading Montessori's pedagogical ideas in the US (Sobe, 2018).

Through support programs and numerous recommendations for and evaluations of school buildings around the world, UNESCO and OECD have both been influential in the transnational movement and entanglement of school design and school curriculum since the 1950s and 1960s. For example, the OECD Program on Educational Building (PEB) began as a forum for discussion and analysis of educational buildings in the early 1970s and laid the foundations for a network of responsible officials in the national ministries of education, led by the OECD. Recently, the OECD has actively promoted the transition to innovative learning environments as a way to align school architecture with the curricular framework for 21st century learning (OECD, 2017).

Not surprisingly, architects have played a profoundly important role in the travel of physical school design. The British architect and member of the London School Board 1871–1889 Edward Robert Robson's famous book *School Architecture* (1874) includes long chapters on his visits to the US, Switzerland, Germany, France, Belgium and Holland. Robson had been traveling "in search of the best schools" and he does not only engage with different architectural design features and building materials. Through a discussion of different teaching methods and their corresponding physical layouts that he encountered in America and continental Europe, he developed design recommendations for the new schools to be built in London (Robson, 1972 (1874)). As an example, the book includes advice regarding the size, layout and not least lighting of classrooms. This advice reflects new approaches to instruction, such as the benefits of strengthening the possibility of surveillance by increasing "the teacher's angle of vision (...) far beyond that of 45 degrees" (Robson, 1972 (1874)). The way in which a small Danish architectural firm became involved in developing modular school buildings in the 1950s offers another example of the great importance of architects' study tours and exchange of ideas for the diffusion and materialization of new educational ideas throughout the 20th century. Contact with the British architect couple Mary Crowley and David Medd had a particular influence on the small company's state-financed design of new learning spaces for the independent and self-reliant student (Coninck-Smith, 2010a,b).

As already mentioned, transnational connections and transfers played an important role in the spread and development of open-plan schooling. In the 1960s and 1970s, architectural designs of US and British open-plan schools traveled across national borders through the work of architects and influential educationalists (Bennet and Hylland, 1979). These architectural models inspired architects and educational policymakers, but they were also often modified in response to national and local policies and educational systems (e.g., Franklin, 2012). The pedagogical ideas tied to open-plan schooling traveled in tandem with the designs themselves, but most often the use and development of open-plan schooling also involved the travel of books and educationalists through study trips and transnational networks involving teachers and school leaders as well as school developers and politicians (McLeod and Rosén Rasmussen, 2021). Thus, the travel of physical design models is not only connected to and brings with it simplified aspects of pedagogy and curriculum; it involves a range of compound ideas, processes and material matters situated within, but also transcending, local and national borders. These ideas, processes and matters entangle and potentially transform the physical design, as well as the associated pedagogical understandings, perhaps also entangling with different regulations and curricular ideas.

Building curriculum and future models of schooling

Significant changes in curriculum, pedagogy and technology have been seen to change the order of the classroom; however, such change has not always been considered successful (Lawn and Grosvenor, 2021). On the contrary, a vast number of studies have pointed out how such intended change is often not realized in the physical learning environment built to incite and enhance curricular transformations. These studies have demonstrated how the absence of change—often accompanied by explicit frustration among school staff—entails “teaching as usual,” despite a new physical environment—sometimes even leading to refurbishments and rebuilds more in line with earlier teaching practices and educational beliefs (Bennett and Hyland, 1979; Cardellino and Woolner, 2020; Gislason, 2015). In some studies, the failure to bring about change is explained by unforeseen aspects of the physical architecture. One example of this is noise problems in some of the open-plan schools in the 1960s and 1970s, with similar problems afflicting some of the open innovative learning spaces built since the turn of the millennium (Shield et al., 2010; Cardellino and Woolner, 2020; Mulcahy and Morrison, 2017). In other cases, teachers’ motivation or their lack of training in and for the new environment have been given as explanations for their reversion to more familiar teaching strategies (Niemi, 2021; Brogden, 2007; Higgins et al., 2005). Recently, interrupted and unclear leadership has been suggested as an obstacle preventing the pedagogical transformation expected to result from profound alterations to school architecture (Daniels, 2019). A wave of so-called post-occupational studies have dived further into the question of the links between physical design and education, exploring what happens when buildings that are expected to inspire and enhance new pedagogical approaches are put into operation (Alterator and Deed, 2018). The answers are manifold but they all engage with the complexity of the issue; for instance, Neil Gislason’s model of how organizational matters, student dynamics and educational culture all help determine the use of a school’s (new) physical design (Gislason, 2018). With the lack of unequivocal answers, more or less all such studies seem to support the argument that there is no causal link between changes to physical learning spaces and pedagogical change (Mulcahy et al., 2015). Despite the missing or unintended effects of new school architecture, the ambition of transforming schooling and learning through educational technology and innovative learning environments has intensified in recent decades (Cardellino and Woolner, 2020; OECD, 2013, 2017; Dovey and Fisher, 2014; Woolner et al., 2018). This is accompanied by the development of strategies for aligning the educational intentions of physical changes with actual teaching practices through collaborative processes (Fig. 8) (Carvalho and Yeoman, 2018; Bøjer, 2019).

As a potential tool of change, the coming together of school architecture and curriculum has generally been future-oriented, sometimes even turning its back on the past. With the persistence of the utopian element of school architecture as a jumping-off point, Keri Facer has addressed the ethical implications of building schools for an idealized and politicized future (Facer, 2018). Facer recognizes how a school building is a “jetty into the future” and how this both concerns the educational vision involved in the design process and the fact that the building will probably survive “into a time that is not now.” Moreover, the future is seen as at the heart of educational discourses among politicians, academics and practitioners in the sense that education is seen as a way to shape, prepare or defend students for or against a projected future. However, Facer also emphasizes the temporality of education itself—how educational processes continuously generate new ideas about the future and the important role played

Fig. 8 School children engaged in collaborative workshops developing ideas and material elements for their (future) school spaces. Workshops held by Rune Fjord Studio. Photographer: Bodil Hovaldt Bøjer.

by dialog between the past and the present. With this in mind, Facer suggests designing schools as laboratories that allow teachers and students to play with the future.

Regardless of the complex relationship between physical design and curriculum in its broadest sense, the importance of the physical learning environment on educational processes is underlined both empirically and theoretically. The current paper's reflections on shifting empirical and theoretical understandings of the relationship between school architecture and curriculum may be helpful in maintaining a more holistic and caring approach to designing school(s), literally and figuratively.

Introduction

Traditionally, the curriculum is perceived to be the domain of teaching staff (Bourner, 2004); something designed by staff and “done to” students. Curriculum has often been considered synonymous with a syllabus or canon of knowledge, captured in a document, which in some countries is considered a legally binding statement of what an institution guarantees a student will be taught. Therefore, students and staff co-creating the curriculum in higher education is a reconceptualization of the way many people think about curriculum—what it is, who does it, and how it is done. Co-creating the curriculum is not a new idea, but it has attracted growing attention over the last decade (Bovill, 2020a; Cook-Sather et al., 2014; Lubicz-Nawrocka, 2020; Mercer-Mapstone et al., 2017). Within recent literature, co-created curriculum is considered to be a dynamic negotiation of learning and teaching between staff and students (Bovill and Woolmer, 2019; Fraser and Bosanquet, 2006).

In this chapter, I will explore the nature of higher education curriculum and definitions of co-creation, as well as outlining the differences between co-creation *of* the curriculum and co-creation *in* the curriculum. I will present a range of theoretical frameworks and models used to inform thinking about co-created curriculum. In trying to understand co-created curriculum, I present some examples from around the world, which help to illustrate the diversity of what is possible. I will also explore some of the benefits and challenges of co-creation. Finally I ask the question of whether we should be offering all students in higher education the opportunity to co-create the curriculum, in the face of the increasing evidence of the benefits from co-creation processes and outcomes. Before proceeding, I make just one note on the text: I use the term staff in this article to refer to both academic staff and professional services staff working in higher education who have any form of responsibility for teaching, learning, assessment and curriculum design.

What is co-created curriculum in higher education?

In order to explore the nature of co-created curriculum in the higher education setting, we need to ask first what is the higher education curriculum? We also need to ask what is co-creation? And finally, what is co-created curriculum in higher education?

What is the higher education curriculum?

The curriculum is frequently considered synonymous with the syllabus. The syllabus is usually a list of topics and concepts which students should be taught, and students are expected to know by the end of a course or program. Where curriculum is thought of in

a similar way to the syllabus, this is a knowledge-centric, often static version of curriculum that relates to the idea of students learning a disciplinary “canon.” This perspective fails to recognize that the curriculum for many scholars and practitioners is a more dynamic process, which cannot exist as a document on a shelf, or without students as part of that process (Barnett and Coate, 2005; Fraser and Bosanquet, 2006).

The curriculum framework from Barnett and Coate (2005) based on empirical research in the UK, highlights the importance of balancing students’ development of “knowing,” “acting” and “being” if students are to be prepared for a complex future world. Typically, higher education curricula emphasize content knowledge or “knowing.” “Acting” refers to putting into practice approaches that are common in a discipline but often tacit to disciplinary experts, emphasizing the skills needed within a particular discipline. And finally, “being” refers to the development of the student as a person, encompassing the idea of how a student takes a stance in relation to the world—“being-in-the-world,” self-realization and capability. Barnett and Coate (2005) highlighted that different disciplines place different emphasis on knowing, acting and being, but all of these elements are essential in any curriculum. These three building blocks of curriculum align well with work by Entwistle (2003) and McCune and Hounsell (2005), who described in their research, students learning “ways of thinking and practicing” in the subject. For example, students need to learn not only biology knowledge, but importantly, also how to practice as a biologist and scientist. Barnett and Coate (2005) envisage the curriculum as a form of engagement, which involves deliberately designing in opportunities for students to engage in knowing, acting and being.

Australian researchers Fraser and Bosanquet (2006) carried out important research that examined how academic staff define curriculum. Participants in their study defined curriculum in four ways: “A: the structure and content of a unit (subject); B: the structure and content of a programme of study; C: the students’ experience of learning; D: a dynamic and interactive process of teaching and learning” (Fraser and Bosanquet, 2006, p. 272). Categories A and B are similar to one another but differentiated by whether the focus is on a course or program, in other words, by the scale of the curriculum. Category C expands the idea of the curriculum to be more than just structure and content, to include students’ perspectives of learning—the teacher provides a framework within which students begin to negotiate the curriculum. Category D sees the curriculum as involving an integral role for students as collaborators in designing curriculum and co-constructing knowledge alongside academic staff. This final definition provides less framing by the teacher than Category C. Both categories C and D move “... away from curriculum as a product provided for students, to a process that enables student learning” (p. 274).

There are other higher education curriculum models and frameworks such as the constructive alignment model from Biggs (1996), which emphasizes an assessment-led, outcomes-focused model of course and program design. Also there is the taxonomy of significant learning from Fink (2003, 2007) and five approaches to curriculum design from Toohey (1999). However, the frameworks from Barnett and Coate (2005) and from Fraser and Bosanquet (2006) are particularly helpful in explaining why many colleagues have come to recognize the role of students in curriculum processes. We also need to acknowledge the key role of curriculum scholars from schools education, particularly those who have promoted the idea of the curriculum as a process (Beane, 1997; Boomer, 1978; Boomer et al., 1992; Eisner, 1979; Joseph, 2011; Stenhouse, 1975). In conceiving of the curriculum as a process, these authors were also seeing the curriculum as an opportunity for students to be involved in decision making about their education. Arguments for process-based definitions of curriculum are often informed by a recognition that the Latin root of curriculum translates as “a race” and its derivative, “currere” as running the race—suggesting a process (Bron et al., 2022; Pinar, 1975). Indeed Boomer “playfully uses the verb ‘curriculuming’ for this, to imply action and process” (Bron et al., 2022, p 3).

What is co-creation?

Co-creation is “the values-based implementation of staff and students working together in an ongoing, reciprocal, creative, and mutually beneficial process to negotiate and share decision-making regarding aspects of higher education curricula” (Lubicz-Nawrocka, 2020, pp. i–ii). This definition captures a sense that co-creation both differs from, and also shares characteristics with, some similar terms which are often used inter-changeably. It can be helpful to think about the terms student engagement, active learning, co-creation and partnership as broadly “an overlapping continuum of student participation where the level of meaningful participation, shared decision-making, shared responsibility and equality increases as you move from student engagement to partnership” (Bovill, 2020a, p. 31). Finally, Iversen and Stavnskaer Pedersen (2017) remind us that both the “co” and “creation” elements signal to us that this is a social process, in which something new appears from that process.

What is co-created curriculum in higher education?

The idea of co-created curriculum is not new. In the early 1900s, Dewey argued for more democratic school classrooms (Dewey, 1916). In the 1960s, Rogers built upon Dewey’s work by proposing alternative approaches to existing formal schooling. He argued students need the “freedom to learn,” emphasizing the learner as a contributor to the learning process, including students co-creating curriculum (Rogers and Freiberg, 1983). In the 1980s, Giroux continued to build upon these ideas in his foundational work advocating for critical pedagogy (Giroux, 1983). Critical pedagogy promoted the idea that students and staff should negotiate learning and teaching in order to co-create new forms of knowledge from their experiences and in order to challenge existing views of the world—ultimately with the goal of students re-creating a new society (Darder et al., 2003; Giroux, 1983). Boomer and colleagues in Australia drew heavily upon the critical pedagogy literature in their work focused on negotiating the curriculum (Boomer et al., 1992). According to Boomer et al. (1992) negotiation of the curriculum relies upon challenging existing

understandings of power relationships in learning and teaching. This legacy from schools education has been influential in higher education, with increasing attention being paid to co-created curriculum in higher education over the last decade in particular.

Co-created curriculum practices have spread across a range of disciplines in higher education, with some scholars claiming the benefits offer alternatives to the neoliberal and marketized university, while others challenge these claims (Gravett et al., 2020; Holen et al., 2020; Waddington, 2016; Wijaya Mulya, 2019). But other common motivations for co-creation often refer to the wish to enhance students' experiences, to democratize higher education, or to offer a more socially just approach to teaching and learning (Lubicz-Nawrocka, 2016; Owusu-Agyeman and Fourie-Malherbe, 2019). Co-created curriculum can be found in many different disciplines, and while not a comprehensive list, examples can be found in: language teaching (Barrineau et al., 2019; Breen and Littlejohn, 2000); teacher education (Bergmark and Westman, 2016; Mihans et al., 2008; Van Werven et al., 2017); geography (Moore Cherry et al., 2016; Hill et al., 2016); ecology (Huxham et al., 2015); environmental justice and environmental history (Barrineau et al., 2019; Fischer, 2005; Grudens-Schuck, 2003; Wilkinson and Scandrett, 2003); gender studies (Kenny, 2019); mathematics and statistics (Delpish et al., 2010; Duah and Croft, 2012); science (Woolmer et al., 2016); engineering (Bovill, 2020a); chemistry (Bengtson et al., 2017); psychology (Bovill, 2020a); business studies, innovation and entrepreneurship (Cook-Sather et al., 2014); medicine (Barrineau et al., 2019; Harden and Fawcner, 2019); nursing (Fawcett and Watson, 2019); film studies (Bell et al., 2019); and classics (Cook-Sather et al., 2014). In addition, there are resources which bring together co-creation examples, research and practice across a diverse range of subjects (Barrineau et al., 2019; Bovill, 2020a,b; Cook-Sather et al., 2014; Mercer-Mapstone and Abbot, 2020).

Bovill and Woolmer (2019) argue that in higher education, it can be helpful to distinguish between co-creation *of* the curriculum and co-creation *in* the curriculum. Co-creation *of* the curriculum involves co-design of an institutional curriculum or a program or course, usually before the curriculum, program or course takes place, and often involving only a selected group of students. In contrast, co-creation *in* the curriculum involves co-design of learning, teaching and assessment within a curriculum, program or course as it takes place, and often involving all students in the class or cohort (Bovill, 2020b; Bovill and Woolmer, 2019). There has been little debate about the connections between these two forms of co-created curriculum, and indeed, many examples of co-creation tend to be one or the other form of co-creation. It appears uncommon for students to be involved in co-creation *of* a curriculum and then also to get an opportunity to make further decisions about this curriculum as a student in the class, taking part in co-creation *in* that same curriculum. There are some examples, (see for example Mihans et al., 2008), but for students to be involved in both forms of co-created curriculum requires co-creation *of* the curriculum to involve future students who will be studying a course or program. In addition, most examples of co-creation *of* the curriculum involve a selected group of students and therefore, even where there has been an opportunity to co-create the curriculum before a course or program commences, the likelihood is that most students in the class will not have had a chance to co-create the curriculum before arriving in class.

Co-creation *of* the curriculum might be expected to focus on decisions about different things than co-creation *in* the curriculum, but in reality, there are examples of co-creation in the curriculum which include decisions about, for example, learning outcomes, method of assessment, and weighting of assessments. However, rules about what is expected to be pre-set in any curriculum before a course starts will differ from country to country and from institution to institution. Building on one of Fraser and Bosanquet's (2006) definitions of the curriculum, as a dynamic negotiation between teachers and students, I argue that it is important we view the curriculum not as something set in stone, but as Breen and Littlejohn (2000, p. 277) argue, "... teachers may need to come to see their own plans for classroom work as simply proposals ... which learners have the right to reformulate, elaborate upon or even reject".

Theoretical frameworks and models

A number of researchers have argued that much of the student engagement, partnership and co-creation literature tends to be atheoretical (Gravett et al., 2020; Macfarlane and Tomlinson, 2017). Yet others have argued a range of theoretical frames are used in partnership work and that there is space for creativity and theories emerging from practice (Matthews et al., 2019). It would be fair to say that some of the partnership literature is small scale scholarship providing examples of partnership in action and tends not to connect to theory explicitly. However to claim that the partnership and co-creation literature tends to be atheoretical may be over-stating this point. In their work Matthews et al. (2019) identified that partnership and co-creation work had previously drawn on the following concepts: threshold concepts, participative reality, communities of practice, student engagement, deliberative democracy, and ecology of participation literature. They also argued that partnership and co-creation work had drawn on the following constructs: identity, power, and gender. In Bovill (2019a) I argue that critical pedagogy has underpinned much of my work, but critical pedagogy also informs much co-created curriculum either explicitly or implicitly. Authors of critical pedagogy literature recognize that all education is political and has a role to play in developing critical citizens who not only contribute to, but also define society. Critical pedagogy promotes: greater freedom for students to make choices and decisions about their own learning; more dialogic student-teacher relationships; and a significant shift in perspective to view the learner as a competent contributor to education (Bovill, 2019a; Giroux, 1983). Using the lens of critical pedagogy enables us to see the potential of co-created approaches to contribute to developing negotiation, citizenship and leadership skills, to transform thinking and practice, and ultimately to change society (Bron et al., 2022). Clearly not all authors and practitioners of co-creation and partnership literature are motivated or influenced by critical pedagogy, but some of the characteristics of critical pedagogy can be found in a great

deal of the discourse. In addition, there are many other frameworks and models which are referenced in relation to co-created curriculum, some of which are described briefly here.

Arnstein's Ladder of Citizen Participation (Arnstein, 1969) has informed a number of adapted models, and it is explicitly translated for higher education co-created curriculum in the Ladder of student participation in curriculum design (Bovill and Bulley, 2011). The Bovill and Bulley (2011) model includes different ladder rungs illustrating different possible levels of participation by students in curriculum design. Arnstein's original work was in the field of town planning, and she expressed a deep frustration with planning approaches where decisions were made democratically only in name—essentially empty claims of participation. Her ladder helped to highlight the lack of power held by citizens in many planning decisions, consistent with the importance of power highlighted by Matthews et al. (2019).

The participation matrix is often used in the business and international development sectors to consider stakeholders' roles in a project—the possibilities include: inform, consult, participate, partnership, or control. Each stage of a project can then be considered in terms of the role each stakeholder adopts. For curriculum co-creation, use of the matrix helps to highlight that different students and teachers can be involved in different ways at different stages of the work (Bovill, 2017). The participation matrix helps to push an existing concept of stakeholder consultation to a deeper level of analysis by highlighting the range of stakeholders involved and the complexity of who should be involved when and in what ways. This tool can enable people to see past simplistic notions of someone being involved or not involved, toward more nuanced negotiation of the different roles people can adopt at different stages of co-creation work. It also moves past business notions of focusing the analysis of stakeholders on whether they are important or influential.

The decision-modes framework from Heron (1992) draws from a humanist perspective to highlight the early decisions made by teachers in learning and teaching collaborations. Heron highlights that in any teaching situation, staff make choices whether to “direct,” “negotiate” or “delegate” authority (Heron, 1992). Direction involves staff making decisions for students, negotiation involves staff making decisions with students, and delegation is where staff step back and students make decisions. Heron (1992) argues that whichever “decision-mode” is used is ultimately decided by staff. He also highlights that these decisions are taken on multiple levels in relation to any teaching. This work is helpful in highlighting the different levels at which teachers and students can co-create, as well as likely patterns of who will be making decisions at each level.

The co-creation of learning and teaching typology (Bovill, 2019b) draws together many previous ideas and models to pose a range of questions to those involved in co-creation work to help them frame their work and be more explicit about the kind of co-creation they are doing. These questions enable distinctions to be made between different forms of co-creation, for example: whole class and project-based co-creation; the focus of co-creation work; which students are involved; and the nature of student involvement. Used at an institutional level, it can enable colleagues to see trends in the kinds of co-creation in practice. It acts as an accessible planning tool, enabling staff and students to be clearer about the kind of work they are planning, implementing or evaluating.

The student roles model (Bovill et al., 2016), highlights four different but overlapping roles students commonly adopt when co-creating learning and teaching: “(1) consultant, sharing and discussing valuable perspectives on learning and teaching; (2) co researcher, collaborating meaningfully on teaching and learning research or subject-based research with staff; (3) pedagogical co-designer, sharing responsibility for designing learning, teaching and assessment; and (4) representative, student voices contributing to decisions in a range of university settings” p. 197–198. The authors highlight differences between the roles in terms of whether they tend to be student or staff-led, and whether students are typically elected, selected or all students have the opportunity to adopt these roles in co-creation. The model particularly highlights differences between representation and other co-creation roles, and echoes the discussion of identity in Matthews et al. (2019).

The students as partners in learning and teaching in higher education—an overview model (Healey et al., 2014) is a commonly referenced model within partnership literature. The model comprises a Venn diagram of overlapping circles: Learning, teaching and assessment; curriculum design and pedagogic consultancy, scholarship of teaching and learning; and subject-based research and enquiry. At the heart of the model is “partnership learning communities.” The model was used as the basis for a systematic review of partnership literature (Mercer-Mapstone et al., 2017) and has been used widely as a reference point in discussions of partnership. It has not been used as widely to inform discussion of co-created curriculum. Perhaps the separation of learning, teaching and assessment from curriculum within the model creates some tensions for conceptualizations of co-created curriculum. If we adopt a process conceptualization of the curriculum, as more than a list of topics to be taught and learned, curriculum will then include learning, teaching and assessment rather than being treated separately from the curriculum, as in this model.

The Value in Use model from Ranjan and Read (2016) highlights the three key concepts of personalization, experiences, and relationships in measuring the value of products within a marketing context. Dollinger and Lodge (2020) apply this model as a lens through which to explore their research findings and to judge the value of partnership to the student experience. They argue there might be benefits for universities to adopt the marketing concept of value to benchmark and assess the student experience.

The student partnership framework (Olsen, 2007) is divided into four quadrants representing different ways of understanding student partnership from an institutional perspective: apprentice; democratic participant; customer or consumer; or follower of political agendas. The roles are influenced by two axes: one which is focused on internal or external pressure toward student participation and the other focused on actors having either shared or conflicting norms and objectives (Holen et al., 2020). These different partnership roles are informed by other frameworks—apprentice, coming from the Humboldt vision of the university; the democratic participant, from a vision of a representative democracy; the customer or consumer, based on a service enterprise vision; and the follower of political agendas, based on viewing universities as places that can influence politics.

The theoretical model for students as change agents from [Dunne and Zandstra \(2011\)](#) is also a model based on quadrants, which focuses on four roles students adopt as change agents: evaluators of their HE experience (the student voice); participants in decision-making processes; partners, co-creators and experts; and agents for change. The two axes divide the quadrants by whether there is emphasis on the university or the student as a driver, and between whether there is emphasis on the student voice or student action. This model connects well with the construct of power noted as important by [Matthews et al. \(2019\)](#), in highlighting the changes in power necessary to enable students to gain agency to make change in their university. The original concept of change agents comes from business models of change.

Although there are overlaps between ideas in some of the models, each individual model or framework offers a lens through which we can conceptualize co-created curriculum (and wider partnership and student engagement initiatives). Each framing has the potential to support greater understanding of co-created curriculum. This is not a comprehensive list of relevant models and frameworks, but simply offers an introduction to some of the useful frameworks available.

Examples of practice

Having explored different ways in which co-created curriculum is conceptualized, it is worth taking a closer look at some of the many examples of co-created curriculum from around the world. I have classified the small selection of examples included here as either examples of co-creation *of* the curriculum or co-creation *in* the curriculum. Note that the examples of co-creation *of* the curriculum more commonly involve selecting a small group of students to be involved. In contrast, examples of co-creation *in* the curriculum commonly involve the whole cohort, class or group of students studying the course. Further examples can be found in [Barrineau et al. \(2019\)](#), [Bovill \(2020a\)](#), [Cook-Sather et al. \(2014\)](#), [Werder and Otis \(2010\)](#).

Co-creation *of* the curriculum

Course design teams at Elon University, North Carolina, USA

Mihans and colleagues describe bringing together a course design team in which students and staff worked together to re-design an existing education course ([Mihans et al., 2008](#)). The 10 person course design team was deliberately made up of more students than staff in an attempt to change the power dynamics typical in curriculum design discussions. The team comprised seven undergraduates, two faculty who taught the course; and one faculty developer. The students included some students who had previously studied the course and some students who were going to be studying the course. The team met about 12 times over a period of two to three months to carry out the course design work. Time was considered a key element of success in this work, with the regular meetings providing opportunities to achieve the course design aims as well as develop strong relationships, trust and shared respect.

Co-creating a science skills curriculum at the University of Glasgow, Scotland, UK

Woolmer and colleagues co-created a new inter-disciplinary science skills course for students from Physics and Astronomy, Geographical and Earth Sciences, and Chemistry ([Woolmer et al., 2016](#)). A staff member and a student from each of the subject areas worked together over the two phases of the project. First, the group surveyed students and staff from all the discipline areas to ask their views about the most important science skills students should learn in their discipline and which of these were currently taught well at the University. Several focus groups also explored these issues in more depth. In the second part of the project, students and staff co-created teaching materials for a new science skills course focused on the key skills identified in the first part of the project, and a plan for a teaching approach for the course based on research into science skills teaching. Students created high quality lecture notes, team projects, laboratory exercises, example sheets and exam questions. This new course ran so successfully in its first iteration that the course credits were doubled and the course expanded further in the following year.

Co-creating a chemistry course at Uppsala University, Sweden

[Bengtson et al. \(2017\)](#) co-created a first year undergraduate chemistry course. The co-creation project was inspired by a downturn in recruitment for the course due to senior students describing the course to junior students as difficult and of limited use. In the first stage of the co-creation process, they interviewed students to ensure their views were heard about the course. The second stage of the process involved creating a development team of students and teachers numbering eight people in total, working together to re-design the ways the course was taught. This involved for example, ensuring active student participation was a key part of every lecture, but also making changes to the course reading list and creating a table of formulas. "A difficult part of the process was to find a balance between defining the project and giving students enough power and freedom" ([Bengtson et al., 2017: 6](#)), an observation shared by many people co-creating curriculum. The changes made to the chemistry course led to much higher levels of student satisfaction with the course.

Co-creating an interdisciplinary program, University of Technology, Sydney, Australia

[Baumber et al. \(2020\)](#) co-created the curriculum for the interdisciplinary final year of a creative intelligence and innovation program. The course program is focused on addressing "... complex real-world challenges through collaboration and mutual learning across disciplines and with a variety of industry, government and community partners." p. 4. The work took place in three stages, the first of which was to hold participatory design sessions with staff and students who were going to be studying the

program. The second stage involved ensuring that all the different perspectives and experiences in the group were fed into the design process. This stage also involved ensuring these processes were documented in order for each stage to inform and enhance following stages. The third stage comprised trying out alternative co-creation approaches with a second cohort of students. The entire process was cyclical and iterative, emphasizing reflection on, and learning from, each stage of the design, and feeding this into the next stages.

Co-creation in the curriculum

Shared PowerPoint slides, University College Northern Denmark (UCN), Aalborg, Denmark

Louise Esko Refshøj and Steffen Holme Helledie at University College Northern Denmark teach a class focused on innovation. They were committed to students being a meaningful part of creating the course, as they recognized that students have ideas about what innovation is before they take a course on innovation. In order to tap into students' existing expertise, they created a shared PowerPoint document and gave all the students editing rights to the document. They asked each student to create a couple of slides that would represent their perspectives about what innovation is. The students created a large set of slides, and as the course progressed, in each class there would be time for students to present their slides to the rest of the class. It was just one element of the course design which helped to communicate to students that they were important contributors and collaborators in learning and teaching (Bovill, 2020a).

Co-creating essay titles, University of Vienna, Austria

Professor Peter Kruschwitz at the University of Vienna teaches Classics, and for many years now, has invited his students to co-create their own essay titles. He provides students with six to eight keywords, and then asks his students to create their essay title based on these keywords. This simultaneously keeps them focused on the topic, but gives them the freedom to choose which elements of the topic they are most interested in and to construct their essay title accordingly. He talks with students about their titles and sometimes suggests changes, but usually on the basis of scope—where essays will be difficult to write because the title is too narrow or too broad. Over the years he has evaluated this work and demonstrated increased grade point averages for students. He puts this down to increased student interest and motivation in their assignments compared with assignments set by the staff (Bovill, 2020a; Cook-Sather et al., 2014).

Co-creating courses within a Masters in Education, Universiti Utara Malaysia, Sintok, Malaysia

Kaur et al. (2019) describe their work to co-create four different courses within a Masters in Education. Each course involved all the students on the course (the 4 courses involved 7, 15, 16 and 28 students) working with the course instructors in partnership for one semester to plan, design and also teach the course. Students worked in small groups and were enabled to select elements of the curriculum that they were most interested in, and then they were provided with the relevant learning outcomes and assessment guidelines. Students and instructors discussed their preferred ways of learning so that this could inform the work they would do to co-create the courses. The students and instructors met throughout the semester to design and enhance the teaching plan. Each course ended up having between two and four sessions which were co-created by students and staff. The staff and students worked alongside each other to teach these co-created sessions. Importantly, Kaur et al. (2019) explore in their research whether some students in an East Asian setting might find co-creation an alien concept, and while some students were a little reluctant (similar to some students in all contexts), ultimately, many students adapted well to co-creating the curriculum.

Co-creating a business course, University of St Andrews, Scotland, UK

Professor Ignacio Canales co-created an Entrepreneurship and Business Planning course with 50 3rd and 4th year students when based at the University of St Andrews. As one of the main assignments for the course, the students are required to work together on group projects to create a business idea. Once they have been assigned to groups and have agreed what they are focusing on, the whole class is invited to share ideas about what they need to learn in order to be able to successfully achieve the group project. All the students and Professor Canales then negotiate sharing out responsibility for reading about, and creating engaging teaching materials to teach the rest of the class about these key ideas (Bovill, 2020a; Cook-Sather et al., 2014).

Benefits

One likely reason for the increased interest in students and staff co-creating curriculum over recent years, is the growing evidence demonstrating the benefits of co-creation. Many of the benefits are connected with student-staff partnership in learning and teaching, but there are many overlaps between the findings from studies specifically focused on co-created curriculum too. Partnership in learning and teaching has been demonstrated to lead to: enhanced engagement and motivation for learning and teaching; increased meta-cognitive awareness of learning and teaching and a more developed sense of identity; and enhanced classroom practices (Cook-Sather et al., 2014). Interestingly, many of these benefits are shared by students and staff, even if experienced in slightly different ways. Mercer-Mapstone et al. (2017) in their systematic review of "students as partners" literature also draw attention to beneficial enhancements for students to their sense of belonging, confidence, positive relationships, and trust.

Bovill (2020b) synthesizes additional benefits specifically demonstrated to result from co-creation of learning and teaching with a whole class of students, which include: enhanced academic performance; greater academic aspirations; enhanced skills development; opening up the learning process to become more transparent; a shift in the focus from grades to learning; increased ownership, autonomy and self-regulation; students feeling valued. Other findings from Bovill (2020b) highlight the role co-created curriculum can play in: providing an opportunity to practise working democratically; enabling students to experience a more equal relationship with a teacher; and the curriculum becoming more socially relevant—the latter findings backed up by other research demonstrating co-created curriculum is considered to contribute to social justice and civic engagement (Bergmark and Westman, 2016; Lubicz-Nawrocka, 2016; Owusu-Agyeman and Fourie-Malherbe, 2019). Finally, co-created curriculum has also been described as an authentic and enjoyable process (Lubicz-Nawrocka, 2019; Temple Clothier and Matheson, 2019).

These are all compelling outcomes, but also important is to try to capture the sense of personal transformation and significance from co-creation experiences. In Lubicz-Nawrocka's (2020) research, she found that every student in her study who was exposed to co-created curriculum (through a range of different co-creation initiatives across Scotland), reported that the co-created course that they experienced at university was the best course they had studied. We should also acknowledge that personal testimonies can be powerful and offer a different, but equally important form of evidence. One student in Lubicz-Nawrocka (2019) comments on her experiences of co-creating curriculum,

to me it is about being conscious, not only about what you are doing, but what you are capable of doing and definitely to challenge staff and other students. ... It is about going to university and not being passive and waiting for people to tell you what to do. It's getting into an environment where you are able to really get your creative side out and trying to see what you can do ... and be confident in what you are doing (p. 207).

Another student in the same study comments,

I was actually considering dropping out throughout last year so having this course to look forward to was the main reason why I stayed really. (Lubicz-Nawrocka (2019, p. 205).

Guy Finkill, in Barrineau et al. (2019), argues that

to experience any other form of education now would feel like nothing less than a fundamental step into the past ... (p. 58).

From a staff perspective:

It was liberating ... we moved from teaching ... that just didn't work to... [teaching] ... that ... was put together in ways that I never even imagined were possible ... so ... it's really transformed how I think about teaching and how I teach

Bovill (2014, p. 18).

Alison Cook-Sather, interviewed at Uppsala University in 2015, also highlights the value of co-creation from a staff perspective

I value your perspectives on what learning is like in my classroom, I can't know that, I can only know what it's like to teach in this classroom but only you know what it is like to learn in this classroom. So you have a perspective that I don't have and that I would benefit from hearing so that I can make sure that the learning is the best experience that it can be for you

Cited in Barrineau et al. (2019, p. 174).

Challenges

We are enculturated to believe that learning, teaching and curriculum design should be done in certain ways in higher education. Therefore, co-creating curriculum requires many students and staff to adapt their approaches to learning and teaching as well as the ways they relate to one another. In other words, for many people, co-creation requires a change of mind-set. It is perhaps unsurprising, therefore, that we sometimes encounter resistance from student and staff colleagues to this suggestion of change (Bovill et al., 2016). Yet, there are many examples of successful co-creation practice, processes and outcomes, which can be used to help overcome this resistance. Other common challenges include the perception that the constraints that exist to changing the way we "do" curriculum are more rigid than they actually are. As an example, professional body requirements in some programs may often set some quite distinct graduate outcomes that students are expected to achieve, yet there is commonly a good deal of flexibility as to how to achieve these outcomes (Bovill et al., 2016; Hutchings et al., 2011).

Bovill et al. (2016) argue that institutional systems and structures often act as a barrier to co-creating curriculum. For example, many institutions have long processes of course and program approval, and large class sizes are common. Larger classes can make co-creation more challenging, although there are some useful examples of co-creation in larger classes (Bovill, 2020a; Cook-Sather et al., 2014). The sustainability of co-creation initiatives has also been highlighted as a potential challenge (Cook-Sather et al., 2014), and another widely discussed challenge has focused on how to ensure co-created curriculum initiatives are inclusive (Dwyer, 2018; Marquis et al., 2018; Mercer-Mapstone et al., 2021).

Colleagues who are less used to teaching and learning in an online environment may struggle to adapt the concept of curriculum co-creation to an online environment. Yet, this is not a concept that “belongs” to in-person, face-to-face settings. This is an approach, a set of values and a mindset, which is not mode- or setting-dependent. The more we share examples and ideas, the more feasible co-creation may seem to those who feel less confident in adopting this approach. Co-created curriculum requires authenticity and sincerity to the offer to co-create, it also requires shared responsibility, respect and reciprocity (Cook-Sather et al., 2014).

Can we afford not to co-create the curriculum?

Many researchers and practitioners around the world are beginning to recognize the powerful possibilities of meaningful student involvement in curriculum design in higher education. Students are key stakeholders in their own learning. Involving students’ multiple perspectives in curriculum design enhances the relevance of curriculum to students as well as their experiences of the curriculum. As we recognize the benefits of co-creation, I have noted that there are increasing calls for co-created curriculum and partnership opportunities to be inclusive. One step in this direction is to co-create the curriculum with a whole class of students (Bovill, 2020b), while not assuming that inviting a whole class or group to co-create means that the offer is automatically inclusive. Particular attention needs to be paid to ensuring underserved students have genuinely equal opportunities to participate. Another area of work related to co-creation, which is gaining increased attention, is the key role played by positive relationships as a powerful driver of successful outcomes for students (Bovill, 2020a; Chickering and Gamson, 1987; Felten and Lambert, 2020; Mayhew et al., 2016). Indeed, positive student-staff relationships are not only a foundational requirement for co-creation, but co-creation leads to enhanced relationships between students and staff, and between students and other students (Bovill, 2020a).

Freeman et al. (2014) in their significant paper outlining the evidence in support of active learning from science, technology, engineering and mathematics, suggest that if active learning were a treatment in a drug trial, the control group in the trial would be suspended, because the evidence is so strong that active learning is beneficial. There is currently less quantitative evidence for co-creation and partnership, due in part perhaps to the nuanced nature of the values and processes involved. Yet as we reflect on the growing evidence base for the benefits of co-created curriculum, including Lubicz-Nawrocka’s (2020) findings that the course which students co-created was the best one they experienced at university, I am left wondering whether we may soon reach a point where we need to ask ourselves if we can justify not providing opportunities for every university student to experience both co-creation *of* and *in* the curriculum.

There are certainly areas of our practice which may not lend themselves perfectly to co-creation. And as with any major shift in the way we think about curriculum, changes will not happen overnight. However, we have witnessed significant change over the last decade as a very small group of enthusiastic staff and student colleagues has grown to become a much larger group; perhaps even a movement of people, committed to changing the way we create curricula with students rather than for students.

Glossary

Art *techne*, a practical knowing, doing, and reflection that involves craft and technique and that is variable and context dependent

Bildung The process of the forming of humans, as well as the determination of the goal and purpose of human existence (Benner and Brüggem, 2004, p. 180)

Didactic transposition (or reduction) The specific arrangement of the pedagogical situation through the educator (often involving simplifications and/or exemplifications) to allow for learning and transformation to happen

Didactics The study (and doctrine) of learning and teaching in general, the professional science of the teacher

Dignity of practice A value and integrity intrinsic to practice that gives it a certain independence from and precedence over theory

Educand The one receiving education as a type of influence, regardless of the context

Educator The one influencing the educand, with an intention to improve them and their relation to the world

Negative education Education or influence of the educand, conceived as a protection of the educand from other influence seen as undesirable

Pedagogy The practice of influencing someone (including oneself) with the intention of improving them, including also both informal and more theoretical reflection on this practice

Pedagogics A rigorous attempt at a theory of education

Representation Deliberately presenting aspects of ways of life and the world to the educand (Mollenhauer, 2014, pp. 34–55)

Science Any rigorous academic pursuit aiming at theorizing any and all realms of the world (e.g. nature and the natural sciences; culture and the humanities or human sciences)

Self-activity Activity on the educand's own initiative, for the educand's own purposes. May be prompted or elicited by an educator

Continental Pedagogy refers to a way of thinking about educational practice that coalesced in Europe some 250 years ago and that continues to be elaborated today. Developed from the Greek παιδαγωγία (*paidagōgīā*; *paidos* = child; *agōgos* = leader) and rendered as *la pédagogie* in French, *pedagogía* in Spanish and *Pädagogik* in German, Continental Pedagogy is based on understandings that are radically different from those taken for granted in education in the English-speaking world.

Continental Pedagogy¹ sees education as being primarily concerned neither with school and curricula, nor with the pedagogy in the English sense of the techniques and politics of teaching (Friesen, 2019). Instead, it begins with the insight that education and

¹The phrase “Continental Pedagogy” represents something of a neologism and a compromise; notably, it does *not* simply refer to the conjunction of continental *philosophy* and pedagogy. Although it has occasionally been used to denote the pedagogical tradition and way of thinking outlined here (e.g., Ponte and Rönnerman, 2009; Kudláčová and Rajskeý, 2019), we recognize that it designates a heterogeneous and heteronomous field or set of fields in Europe. Continental Pedagogy is like continental philosophy in that it is much more expressive of Anglophone awareness than of any European self-descriptions.

pedagogy are both about the influence that is exercised by one person or group (i.e., the educator) on another (i.e., the educand), and that this influence exists in special relation to the world. The resulting configuration of self, other and world forms what has been called the “pedagogical triangle” (Fig. 1; e.g., see: [Briançon, 2019](#)). Within this configuration, pedagogy is particularly concerned with the personal experience of the educand with the educator (i.e., the pedagogical relation; [Friesen, 2017](#)) and with the educand’s relationship with the world (*Bildung, formación, le formation*).

Defining Continental Pedagogy through the question of influence and the tripartite configuration of self, other and world gives it a distinctive emphasis on basic relations—ones that can be found in many spheres of human activity. The triangular paradigm of this pedagogy maps to a wide variety of life experiences and human interactions—not at all limited to modern or Western cultures—and it offers its own modes of knowing, reflecting and acting.

The relationship between educator and educand has traditionally been framed intergenerationally as the relation of *adult* and *child*. In this context the central point of pedagogy has been formulated in various ways: As “what ... the older generation ... want[s] with the younger” ([Schleiermacher, 1826/2022](#), p. 46), as “the reaction of society to the fact of [human] development” ([Bernfeld, 1925/1973](#), p. 90) or as “our attitude toward the fact of natality” ([Arendt, 1958/1968](#), p. 196). Correspondingly, Continental Pedagogy does not regard education as something to be studied primarily through disciplines like sociology or psychology. Instead, it sees pedagogy as designating a distinctive perspective, as constituting an autonomous discipline with its own, specifically pedagogical questions, terminology, and ways of knowing.

Continental Pedagogy also represents a tradition of thought in which theoretical and reflective texts—whether ancient or modern, fictional, philosophical, or theological—are seen as providing a general framework for its evolving questions and changing responses to them. Continental Pedagogy has reflected the influence of the Enlightenment as well as of Romantic, conservative and liberal cultural moments. Particularly in resonance with its Romantic inheritance, Continental Pedagogy today constitutes a site of resistance to neoliberal influences that continue to dominate educational policy and practice (e.g., see: [Horlacher, 2016](#), pp. 118–129; see also [Meirieu, 1996](#)).

Curriculum Studies—whether conceived by Franklin Bobbitt, Ralph Tyler or reconceptualized by [Pinar \(2019\)](#)—clearly differs from Continental Pedagogy in its focus and emphases. While Continental Pedagogy starts with a relation between educator and educand situated in the world, Curriculum Studies begins with the *experience* of the *student* in specifically *academic* settings. It focuses on how this academic experience is formed or manipulated—for better or worse—through specifically *institutional* instrumentalities. Nonetheless, some contemporary curriculum theorists have referred to Continental Pedagogy (as defined here) as the “tradition of *Bildung/Didaktik*” and characterized it as yet another type of “curriculum theory” (e.g., [Autio, 2014](#); [Pinar, 2014](#), p. 2). As this article demonstrates, however, the tradition of Continental Pedagogy not only claims a broader conceptual and practical terrain than Curriculum Studies, it also predates it by centuries. Finally, Continental Pedagogy’s personalized non-psychological and -managerial account of education also presents an alternative to instrumentalization long decried in reconceptualist Curriculum Studies.

This article provides an overview of the theoretical and practical domain constituted by Continental Pedagogy, emphasizing key aspects of its history and theory. It concludes by suggesting ways of reconsidering its relationship to Curriculum Studies and by emphasizing how this pedagogy offers ways of knowing and acting that are themselves irreducibly educative or *pedagogical*.

Pedagogy: structures of relation

As one of the first to provide a formal, theoretical account of pedagogy as a field, F.D.E. Schleiermacher (1786–1834) identified the temporally situated relation between the older and younger generations as the basis not just for all educative activity, but for pedagogical theory itself:

A significant part of the activity of the older generation extends toward the younger, and it is less complete or perfect, the less aware the older generation is about what it is doing and why it is doing it. Therefore, there has to be a theory that is based on the relation of the older generation and the younger This relationship between the older and the younger, and the obligations of the one to the other, form the basis on which we will build everything that lies in the scope of our theory (1826/2022, p. 46).

The starting point for Schleiermacher’s theory is the relation of the older and younger generations and their time-bound situation in the world. Within this context, it is the “response” of the older generation that serves as the basis for subsequent pedagogical action and reflection. These and other elements of Schleiermacher’s definition are later reaffirmed and reformulated by Hannah Arendt (1906–1975) an admirer of Schleiermacher’s: “What *concerns* us all is the relation between grown-ups and children in general or, putting it in even more general and exact terms, our *attitude* toward the fact of *natality*” (1954; p. 196; emphases added). In simple and traditional terms, then, pedagogy is a disposition, a way of knowing and thinking begins with the older generation asking itself about its relationship with and its response (or *responsibility*) to the younger. Arendt makes it clear that this concern entails more than just activity and obligation in some general sense; she explicitly positions educators in relation to those being educated as “representatives” of the world, as introducing the educand or child to the world.

Fig. 1 The pedagogical triangle, showing the relationships between the educator, the one being educated, and the world. Each relationship brings with it different qualities, roles and purposes. The significance of the educator's influence on educand-world relation (indicated by the dashed vertical line) is discussed below (Illustration by authors).

Insofar as the child is not yet acquainted with the world, he must be gradually introduced to it ... the educators here stand in relation to the young as representatives of a world ... it is as though he [the educator] were a representative of all adult inhabitants, pointing out the details and saying to the child: This is our world (1954, p. 189).

As discussed below, the representational and mediating acts of pointing and showing have multiple meanings for pedagogical theory and practice. More important, though, are the three components that constitute this particularly pedagogical situation and their interrelationship. Educand, educator and world together constitute the fundamental structure of pedagogy, the pedagogical triangle (Fig. 1). Each relationship within this triangle—the educator's relation to the educand, the educator's relation to the world, and the child's or educand's relation to the same—constitute the sides of this triangle. As the descriptions of Arendt and Schleiermacher indicate, each relationship in this triadic configuration has a particular character: The *educator's* relationship to the *one being educated*, as Schleiermacher puts it, is a matter of "activity," "awareness" and obligation;" for Arendt, it implies a role for the educator that is particularly "representative." This special relationship is known as the "pedagogical relation"—one characterized by the intention of the educator specifically to influence the educand. More specifically, its orientation and purpose is to change the educand or child's own relation to the world—for example, to have them relate to it with greater familiarity, involvement and investment. In this context, the relation of the *educator* to the *world* takes on a character that it generally does *not* possess outside of pedagogical situations. It is *not* one, for example, where the educator works either to satisfy their own purposes or to address the demands that the world may place upon *them*. It is not a relation of expertise, but rather one in which the educator engages with *the world in terms of its significance for the educand*. For example, as Arendt points out, it is one in which the educator "introduces the world" in various ways, for example, by "pointing out the details" in relation to the child. It is also one in which the educator helps the educand, in part by showing them what is like to be a person who is simultaneously free and responsible. Arendt has the educator say to the one being educated: "this is our world." Through the educand's *Bildung*, their rich and variegated engagement with the world, these words may gradually change in significance: From articulating a kind of claim or challenge to more a statement of fact.

The three relations that constitute the sides of the pedagogical triangle can also be characterized more concretely and pragmatically: The relation between educator and the one being educated encompasses the parent-child and teacher-student relations, and unavoidably entails a personal dimension. The "world" in this sense can refer to the material and natural world, the familial, social and political one, and even the world constituted by one's own self or psyche. The world in this sense has been understood as (human) culture, and in more formal settings, as (educational) "content" (Klafki, 1958/1995)—with the educand's relation to it understood in terms of "knowledge," *savoir* (Houssaye, 2014). *Educand* and *world*, meanwhile are linked through activities like study, play and exercises, through personal interest, life circumstances and through knowing itself. Jean Houssaye, whose work has been widely used in French teacher education, indicates how particular types of educational processes tend to be associated with the specific relationships or "axes" in the pedagogical triangle: "teaching ... favors the teacher-knowledge axis," "learning favors the student-knowledge [or -world] axis," and the teacher-student axis is where Houssaye locates "formation," the French correlative for *Bildung* (2014, p. 12). These relations and the key process of change they can imply provide the outline for much of the remainder of the article and can be summarized as follows:

- **Educator-educand:** a personal pedagogical relation, formative for the educand, allowing the most direct form of educator influence.
- **Educator-world:** a relation focused not on expertise, but on understanding how the world is relevant to the educand, with the aim of improving the educand's relation to it.

- **Change in the Educand-World Relation:** insofar as the educator works to change the educand-world relation, the educator can be said to have their own pedagogical relation to this relation, as indicated by the dotted vertical line in Fig. 1. Educating means to engage with the Educand-World relation in order to change it.
- **Educand-world:** the relation that is the focus of the educator's intention and didactic efforts. Educand and world, meanwhile, are joined through formative experience.

Educator-educand relation: the pedagogical relation

Establishing the relation

Given that it is marked by purpose and intention, the educator's relationship to the one being educated tends to arise deliberately, often through an inaugural moment or explicit decision. Plato's *Republic* (375 BCE/1997), a text that has long served the West as a paradigm for pedagogy, illustrates this through the Allegory of the Cave. The prisoners shackled in the depths of the cave must first be freed from their chains, and then very deliberately "compelled" and "dragged ... by force, up the rough, steep path ... into the sunlight" (515 e). Socrates asks: "wouldn't he be pained and irritated at being treated that way ... [and] unable to see a single one of the things now said to be true?" (516 a). Being thus influenced, gaining insight into the truth, having one's relation to the world changed, can on this account verge on the traumatic. It highlights that the relation of educator and educand requires concerted care and effort on the part of the one educating.

The pedagogical triangle, it should be noted, is here realized as a relation *not* between adult and child—in clear distinction to Schleiermacher's and Arendt's characterizations. It instead arises between adults, between those who are prisoners of their own ignorance and others who undertake to liberate them, with their relation to the world characterized by the morally and epistemologically charged relation between darkness and light, bondage and freedom. Those acting as educators very intentionally change or improve this relation, moving it from imprisoning darkness to enlightened liberation.

Almost 2000 years later, the relationship between educator and educand was recast in the context of what can be regarded as another educational "primal scene." Taken from J.A. Comenius' 1658 *Orbis Pictus* or; *the Visible World*, one of the first picture books for children, it shows an old man pointing and speaking to a child, saying "come boy, learn to be wise" (Fig. 2). The old man can be seen as inaugurating the relation through his gesture as a specifically *pedagogical* relation—one that brings with it the experience of a particularly pedagogical space and time: Space is marked by proximity of adult and child ("come, boy") and time, at least implied by a concern with the *future* ("learn to be wise"). The rest of Comenius' book can be seen as a vast elaboration on this space and time, and of the representative role of the educator as outlined by Arendt. For it goes on to show all aspects of the world and history—as they were then known—not only to one child, but in multiple languages and to a vast range of readers.

Despite the considerable and wide-ranging effort that can be involved, the entry into the space and time of pedagogy is not always explicitly invoked or announced by the educator. In the Romantic novel of education, *Emile; or on Education*, J.J. Rousseau (1712–1778) describes what he calls a "negative education." This is one in which any deliberate or explicit pedagogical plans or intentions are carefully hidden from the educand, the young Emile. Rousseau argues that

the first education ought to be purely negative. It consists not at all in teaching virtue or truth but in securing the heart from vice and the mind from error. If you could do nothing and let nothing be done, if you could bring your pupil healthy and robust to the age of twelve ... at your first lessons the eyes of his understanding would open up to reason (1762/1979, p. 93).

Fig. 2 The pedagogical "primal scene"—with educator, educand and world in indexical interrelation—as shown on the first page of Jan Amos Komenský's (Comenius; 1592–1670) *Orbis Pictus* (Public Domain).

In this initial negative education, the pedagogue works largely if not exclusively not to influence the child directly, but to shield the him or her from damaging external influences. Philippe Meirieu observes that Rousseau's vision has "become the starting point of all pedagogies that want to place the child's activity at the heart of their approach" (p. 83). It entails a pedagogical relation between tutor and child that lasts multiple years (as it would between parent and child), but one—in distinction to Comenius' pedagogical "scene"—in which any direct pedagogical influence is itself hidden from view.

The personal character of the relation

Herman Nohl (1879–1960), whose account is used here as an example, coined the phrase "pedagogical relation" early in the 20th century. He describes it as arising not through specialization or subject-matter expertise, but in terms of a basic attitude or stance (*Grundeinstellung*) taken up by the educator:

This basic stance ... is decisively characterized by the fact that its perspective is unconditionally that of the child or student ... This means that its task is not to draw the child towards ... specific, predetermined, objective goals [of] the state, the church, law, the economy Instead, it sees its goal in the subject and his/her physical and *personal* realization or unfolding. That this child here comes to his life's purpose, that is [the] ... autonomous and inalienable task [of this pedagogy] (1926/2022, p. 65; emphasis added).

Following Rousseau, Nohl here depicts the role of the educator as a largely "negative" one of protection and preservation—from influences of the state, law and economy. Nohl's point is to allow for the uninhibited flourishing of the nascent personality of the child—the development of the "life purposes" that dwell within the child and that have yet to clearly emerge. As a result, the educator fulfills not just a professional but also a personal role: "The basis of education," as Nohl later remarks, "is the passionate relation between a mature person and one who is becoming specifically for the sake of the latter, so that he comes to his life and form" (1933/2022, p. 79).

The pedagogical relation is in this sense an *asymmetrical* one: The educator is there for the educand or child in a way that the child is simply *not* for the educator. This personal "relation of the educator to the child," Nohl continues, "is always doubly determined: by the love for the child as he is and by the love for his educational goal, the child's ideal" (p. 80). This means that educators must balance their engagement with the child between the wants of the present and expectations for the future. The fact that the pedagogical present is in tension with the future in this way further distinguishes the "time" of pedagogy from everyday temporality. As Schleiermacher points out (see, 1826/2022, pp. 50–56), our being with children is neither marked by sustained indulgence in the present nor by the continuous "sacrifice" of present enjoyment for the future (as might happen at work). Nohl explains that the "peculiar opposition and entwinement of two directions of work [oriented the present and future] constitutes the pedagogical stance and gives the educator a singular distance to his subject as well as to his child or student. In its most refined expression," Nohl concludes, "this distance is called pedagogical tact" (1933/2022, p. 81). This tactful disposition and the distance it implies is illustrative of the space of pedagogy, as understood in this case—one in which the educator gives the child room to become themselves, but remains close enough to help.

In both Comenius, Rousseau and Nohl (and also in many more recent conceptions), the relation between educator and educand is understood as a one-to-one relationship. The influencing constitutive of pedagogy, however, is in reality often directed at multiple individuals. Many Continental theorists have thus understood educator, educand and the educational process as situated in a special type of community. For example, the Swiss educational reformer, Johann Heinrich Pestalozzi (1746–1827), expressed in 1799 his desire to transform an orphanage he was setting up "into the spirit of a single large household"—a domestic community in which Pestalozzi himself be the *pater familias* (1799/2022, p. 21). In this role, Pestalozzi sought to cultivate the minute but practical interdependencies of everyday domestic life—ones still indispensable to the development of trust and wellbeing of children today. "In this way," Pestalozzi explains, "the children may be reminded of their own feelings and supplied with a moral and communal understanding of their lives and interrelationships" (1799/2022, p. 21).

In the pedagogical relation, finally, the educator educates through their own self and via the dimensions of the relation itself. Here, the educator *may* serve as a role model, even a representative of all adults or humanity. But what is more important is that they still remain a particular person, with their individual love for the educand, and their own ways of relating. Only by being with a *particular* other can the educand be sensitized to "their own feelings" and develop an "understanding of their lives and interrelationships" in ways that are practical, moral, communal and personal. In this sense, as Houssaye points out, pedagogical relations can themselves be profoundly formative, an intrinsic part of the process of *Bildung*.

The educator-world relation

As mentioned, in relating pedagogically to the world, the educator is not necessarily concerned with knowing or improving the world for *its* sake, but rather, for the sake of the one being educated. The educator's relation to the world is thus *not* one marked by expertise, by a focus on some specific aspect of the world to the exclusion of the others. Just as the educator is not necessarily a subject-matter expert, the goal of pedagogy is not fulfilled via the development of new experts in science, math or any other

subject. Instead, its goal is the development of “well-formed laypersons” (*gebildete Laie*), well-rounded individuals ready for participation in democratic society (Klafki, 1958/1995, pp. 17–18).

Educators engage with the world for the sake of the educand, working to influence the educand’s relation to the world by mediating it in various ways for them. Initially, parents or guardians are generally the best educators of their children. This is not because of what parents may know about the world, but because they have the most developed relationship with the child. They are in the best position to know the relevance of things in the world to the child (e.g., bed-time, a favorite toy) and how to change and improve their child’s relation to them. Like the one being educated, educators have direct access to the corner of the pedagogical triangle designated as “world,” allowing them to develop some sense about how the child or educand sees it while simultaneously showing positive ways of relating to it.

The educator must continuously sense the way of trying to shape the educand’s relation to the world (through the educator-educand or the educator-world relations) that would make a desired improvement most probable. This is what defines the educator’s professional knowledge and ultimately what represents their ability to educate. Those who are most effective as pedagogues are able to change the relation of the educand with the world—whether it is the physical or human world or the world of the educand’s own mind and emotions.

Changing the relation between educand-world: didactics

The techniques that the educator can use to change the world-educand relation are known collectively as “didactics,” *didáctica*, *la didactique*, *Didaktik*. These all trace back to the Greek root to “show” or “point,” with didactics as a pedagogical topic or specialization receiving one of its earliest treatments in *Didactica Magna* (1657) by Comenius. “Didactics” can be interpreted very broadly or narrowly: as referring to all educating and learning, to practices of showing, pointing and clarifying in general, to matters of formal instructional content and technique, and to these matters specifically as they apply to one educational subject area (Gundem, 2000; Plaisance and Vergnaud, 1993). Following Künzli (2010) it is possible to understand the different sides of the pedagogical triangle as corresponding to different but mutually interpenetrating didactical emphases or approaches (i.e., “pedagogies” in the English sense): (1) The *educator-world* side corresponds to a “representational” approach to didactics; (2) the *pedagogical relation* to a communicative one; and (3) the *educand-world relation* to one that is experiential.

Emphasizing the educator-world relation: representation
